Abstract

Text-to-image diffusion models are increasingly distilled into few-step variants and being deployed to enable fast inference. However, their ability to generate harmful or undesired content poses significant safety risks. Data-driven unlearning methods suppress targeted generations by fine-tuning model weights using specialized unlearning objectives. However, directly transferring these objectives to few-step distilled (FSD) models can yield unfavorable trade-offs between targeted suppression and generation utility. Furthermore, performing unlearning on the non-distilled base model and subsequently re-distilling it to obtain an unlearned FSD model incurs substantial computational and time overhead, making it impractical in many settings. Hence, we address this limitation with a preference-driven unlearning framework that revisits Direct Preference Optimization (DPO) for diffusion models. We show that standard DPO and its unlearning derivatives, formulated around noise-prediction error, transfer poorly to FSD models due to their altered generation dynamics. To overcome this, we introduce a modified preference optimization formulation explicitly aligned with the few-step generation properties, *enabling direct concept removal in FSD models* while preserving few-step efficiency and maintaining strong retention of desirable (non-targeted) capabilities. We evaluate our framework primarily on identity and NSFW (nudity) removal tasks and also extend our method to object-level unlearning. Extensive experiments demonstrate consistent and effective forgetting, and strong retention performance, establishing our method as a practical and principled solution for unlearning in FSD models.

1 Introduction

Text-to-image (**T2I**) diffusion models underpin modern generative visual synthesis, enabling high-quality and controllable image generation [100, 75, 74, 70]. However, their success has amplified concerns about undesirable generations [66, 13, 73, 78, 38], driven by unsafe or identity-specific content in large-scale training data [79]. Open-weight *Stable Diffusion* (**SD**) models [74], widely accessible via *HuggingFace* [7], can generate celebrity identities or not-safe-for-work (**NSFW**) content such as nudity. Safety filters are often bypassable via prompt obfuscation or multilingual cues [95, 55, 78, 88, 96], motivating *targeted unlearning* to remove specific concepts while preserving utility [14, 55, 31, 32, 66, 29, 50, 93, 68, 92, 39, 105].

Concurrently, T2I models are distilled into *few-step* variants [82, 59, 77, 76, 98, 97, 19, 90, 106, 107, 21] for efficient inference. These *few-step distilled* (**FSD**) models reduce sampling from 50–100 sampling steps [74, 81] to 2–8 steps, typically via student reparameterization and teacher-guided training [82, 59]. This alters generation dynamics: FSD models commit early with limited intermediate exploration (Figure 1A). Also, undesirable concept residues from the *base model* (**BM**) can transfer to, and even be amplified in, FSD models (Figure 1B), making post-distillation safety critical. A naïve solution—first unlearning on the BM and then re-distilling—assumes that unlearning

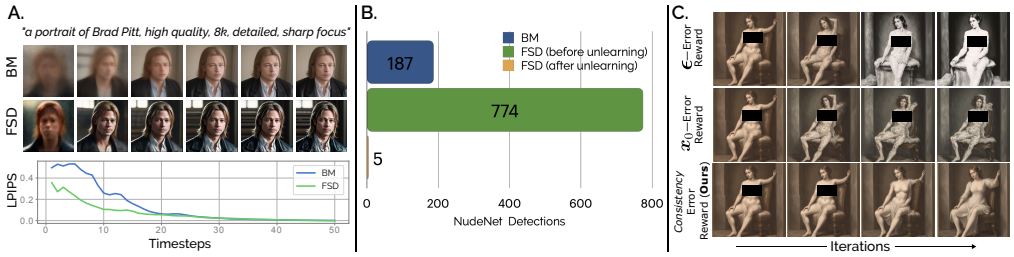

Figure 1: **A.** *LPIPS-to-final vs. timesteps for the base model (BM) [4] and its few-step distilled (FSD) variant [5].* BM follows long, weakly constrained trajectories, while FSD shows steep LPIPS decay, committing within a few steps, limiting mid-path adaptability. **B.** *Severity of unsafe generations in FSD.* FSD model shows elevated detections pre-unlearning compared to its BM, which our method markedly reduces. **C.** *SD-Turbo [10] unlearning dynamics*. Our method (last row) based on consistency error shows stable, gradual and effective unlearning during the course of training.

effects transfer faithfully through the distillation process [59, 97], an assumption that is not guaranteed in practice [85, 36]. Moreover, this pipeline incurs substantial computational overhead (*e.g.*, Luo *et al.* [59] report 32 A100 GPU hours, while Yin *et al.* [97] report 36 hours on 72 A100 GPUs). Since the FSD model is ultimately the deployed artifact, it is both necessary and desirable to directly unlearn undesirable properties on the FSD model itself.

Preference-based methods such as direct unlearning optimization (**DUO**) [66] and **SafetyDPO (AlignGuard)** [54] that are based on direct-preference optimization (**DPO**) [72, 89] have shown *robust* [66] and *scalable* [54] T2I unlearning while enabling *fine-grained control* [66, 41], by contrasting preferred and dispreferred samples using noise-prediction errors along denoising trajectories. However, these objectives were developed primarily for conventional diffusion models using noise-prediction losses. Their suitability for FSD models requires reconsideration because distillation changes generation behavior and, for consistency-style models, the final-output parameterization [59, 48]. In our experiments, directly transferring these objectives can produce unfavorable unlearning–utility trade-offs; see Figure 1C. We identify this *objective dissonance* as the key bottleneck.

We propose ***Consistency-enforced Preference-driven Unlearning*** (CePU), a framework tailored to FSD models. Instead of noise-prediction error [89], CePU (pronounced "C-P-U") uses *consistency* error [82], *i.e.*, discrepancy between clean-sample predictions at adjacent noisy timesteps, capturing the intrinsic few-step inductive bias [22, 82]. Relative consistency errors define a surrogate preference reward that encourages lower errors for preferred samples than for dispreferred samples, measured against the frozen reference model. Notably, directly unlearning on the FSD model achieves performance comparable to unlearning on the BM followed by distillation (Appendix D), while requiring only ≈ 15 minutes on a single A5000 GPU, highlighting the practicality of post-distillation unlearning.

We evaluate CePU on identity removal and nudity suppression, including red-teaming prompts [88, 95, 96, 23, 78]. Since FSD models can generate unsafe content even without explicit prompts (Figure 5), this provides a stringent testbed. We further analyze utility–unlearning trade-offs and extend CePU to object-level unlearning.

In summary: ❶ We identify a fundamental *dissonance* between noise-prediction-based preference unlearning objectives and FSD dynamics (Section 2.2). ❷ We propose CePU that seeks to alleviate the *dissonance* with consistency-based rewards aligned with few-step generation (Section 2.4). ❸ We demonstrate effective unlearning across identity, nudity, and object-level settings and analyze utility–unlearning trade-off *Pareto* fronts to understand the trade-offs across various methods and model families (Section 3).

2 Background, Observation, and Methodology

2.1 Unlearning as Preference Optimization

Given a pair $(\boldsymbol{x}_0^+, \boldsymbol{x}_0^-)$ with $\boldsymbol{x}_0^+$ preferred over $\boldsymbol{x}_0^-$, DPO-style optimization favors the preferred sample relative to a reference model. For our analysis, we introduce timestep-conditioned clean-sample densities $p_\theta^{(t)}$ and $p_\phi^{(t)}$ and consider the following preference objective:

$$\min_\theta -\mathbb{E}_{(\boldsymbol{x}_0^+, \boldsymbol{x}_0^-, t)} \left[\log \left(\operatorname{sig} \left(\beta \left(l_\theta(\boldsymbol{x}_0^+ | \boldsymbol{x}_t^+, \boldsymbol{c}) - l_\theta(\boldsymbol{x}_0^- | \boldsymbol{x}_t^-, \boldsymbol{c}) \right) \right) \right) \right], \tag{1}$$

where the log-likelihood ratio $l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t, \boldsymbol{c}) = \log\left(p_\theta^{(t)}(\boldsymbol{x}_0|\boldsymbol{x}_t, \boldsymbol{c})/p_\phi^{(t)}(\boldsymbol{x}_0|\boldsymbol{x}_t, \boldsymbol{c})\right)$ serves as an implicit reward, $\mathrm{sig}(\cdot)$ is the sigmoid, and β controls the alignment–regularization trade-off.

For diffusion models, Wallace *et al.* [89] derive a tractable objective:

$$\mathcal{L}_{\texttt{Diff-DPO}}(\theta) = -\mathbb{E}_{(\boldsymbol{x}_t^+, \boldsymbol{x}_t^-, \boldsymbol{c}, t)}\left[\log\left(\mathrm{sig}\left(-\beta(\Delta_\theta(\boldsymbol{x}_t^+, \boldsymbol{c}) - \Delta_\theta(\boldsymbol{x}_t^-, \boldsymbol{c}))\right)\right)\right], \tag{2}$$

where $\Delta_\theta(\boldsymbol{x}_t, \boldsymbol{c}) = \|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t, \boldsymbol{c})\|_2^2 - \|\epsilon - \epsilon_\phi^{(t)}(\boldsymbol{x}_t, \boldsymbol{c})\|_2^2$, and $\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon, \epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})$. Here, α_t is the cumulative signal coefficient of the forward process (often denoted $\bar{\alpha}_t$ [44]), with $\alpha_0 = 1$. $\boldsymbol{x}_0$ is the clean data sample, and $\boldsymbol{x}_t$ is its noised version under the forward diffusion process [81]. This formulation replaces explicit reward modeling [65] with relative comparisons in noise-prediction error. This perspective naturally extends to preference-based unlearning [66, 54]. Here, $\boldsymbol{x}_0^-$ corresponds to outputs exhibiting the targeted undesirable or unsafe concepts, while $\boldsymbol{x}_0^+$ denotes preferred alternatives. The objective thus encourages the model to prefer $\boldsymbol{x}_0^+$ over $\boldsymbol{x}_0^-$, effectively suppressing undesirable generations. Importantly, both likelihoods are conditioned on the same prompt $\boldsymbol{c}^-$ (dispreferred class/concept/prompt) that elicits the dispreferred sample $\boldsymbol{x}_0^-$, ensuring that unlearning targets the undesirable generation context.

2.2 Limitations of Preference-based Unlearning on Few-Step Distilled Models

Preference-based methods have demonstrated strong post-training unlearning for conventional diffusion models [54, 66]. However, when applied to FSD models, directly optimizing Diffusion-DPO (2) (and its unlearning variants [54, 66]) yields markedly weaker unlearning, despite identical preference supervision. This discrepancy points to a fundamental objective mismatch.

Diffusion-DPO models preferences through noise-prediction ($\boldsymbol{\epsilon}$) errors, using $\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2$ as the implicit reward signal in $\Delta_\theta(\boldsymbol{x}_t, \boldsymbol{c})$ (2), serving as a proxy for the relative likelihood. Under standard diffusion parameterization, this is well-justified: the $\boldsymbol{\epsilon}$-error is equivalent (up to a scalar) to the sample-space denoising error $\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2$ or simply $\boldsymbol{x}_0$-error [44, 48]. Assuming the forward process $\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon$ and the posterior mean predictor (**PMP**) parameterization $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = (\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t))/\sqrt{\alpha_t}$ [44, 81], **Lemma 1** (proof in Appendix C.1) formalizes this equivalence, implying that optimizing $\boldsymbol{\epsilon}$-error implicitly optimizes the $\boldsymbol{x}_0$-error.

Lemma 1. *Given $\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon$ with $\epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})$ and the PMP parameterization $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = (\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t))/\sqrt{\alpha_t}$, we have*

$$\left\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\right\|_2^2 = \tfrac{1-\alpha_t}{\alpha_t}\left\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\right\|_2^2, \tag{3}$$

yielding identical descent directions up to a scalar.

This equivalence need not hold for the final output of an FSD model that uses an alternative parameterization [59, 82]. For example, Latent Consistency Models (**LCMs**) [59] parameterize $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ as:

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = c_{\text{skip}}(t)\boldsymbol{x}_t + c_{\text{out}}(t)\boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t), \text{ and } \boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t) = \left(\tfrac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}\right) \tag{4}$$

where $c_{\text{skip}}(t)$ and $c_{\text{out}}(t)$ are timestep-dependent coefficients [59]. This formulation belongs to the broader family of parameterizations studied by Karras *et al.* [48]. For this consistency-style parameterization, the simple proportionality between noise-prediction error and final-output reconstruction error does not generally hold. The standard PMP case is recovered when $c_{\text{skip}}(t) = 0$ and $c_{\text{out}}(t) = 1$, as in **Lemma 1**. This motivates reconsidering noise-prediction error as a proxy for the final-output reconstruction error in such models. Empirically, the corresponding preference objective can yield an unfavorable unlearning–utility trade-off, as illustrated in Figure 1C (first row). A natural alternative is to use the primary $\boldsymbol{x}_0$-error $\left(\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2\right)$ instead of $\boldsymbol{\epsilon}$-error, which is invariant to the $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ parameterization. However, the $\boldsymbol{x}_0$-error fails to encode the few-step inductive bias: it neither reflects nor preserves the compressed generation dynamics induced by distillation, see Figure 1C (second row). Consequently, optimizing using the $\boldsymbol{\epsilon}$ or $\boldsymbol{x}_0$-error as the reward signal risks ineffective unlearning in FSD models.

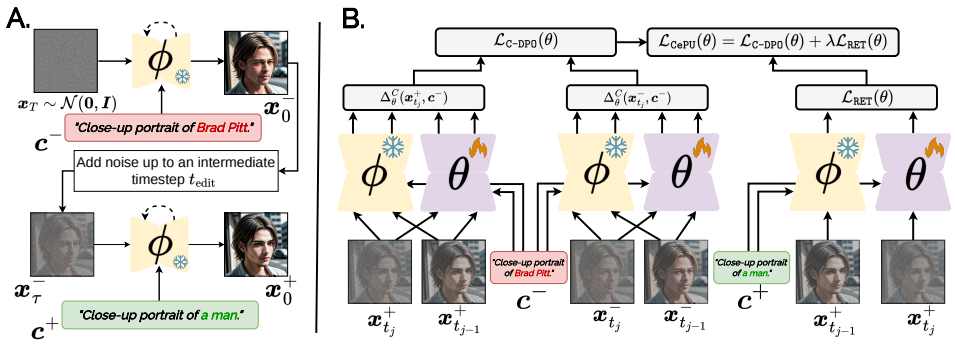

Figure 2: **A.** *Paired data generation via SDEdit [62].* Starting from an unsafe image $\boldsymbol{x}_0^-$ (prompt $\boldsymbol{c}^-$), SDEdit at a mid timestep t_{edit} yields a safe counterfactual $\boldsymbol{x}_0^+$ (prompt $\boldsymbol{c}^+$) that preserves the layout while removing the targeted concept. **B.** *CePU overview.* For each pair, we sample adjacent steps t_j, t_{j-1}, and compute stepwise *consistency* deltas Δ_θ^{C} using the trainable model θ and frozen reference model ϕ, and optimize the $\mathcal{L}_{\texttt{CePU}}$ objective (14) and update θ; the retention regularization term $\mathcal{L}_{\texttt{RET}}$ (weight λ) (13) helps further control the overall generation utility.

2.3 Rectifying Dissonance via Consistency

The preceding analysis reveals a fundamental objective *dissonance*: $\boldsymbol{\epsilon}$-error–based rewards do not faithfully reflect the generation dynamics of few-step distilled (FSD) models. Any remedy must therefore (i) respect the output parameterization, *e.g.*, (4), and (ii) preserve the few-step inductive bias induced by distillation, which the conventional $\boldsymbol{x}_0$-error fails to capture.

We address this by operating in the sample space while explicitly encoding few-step structure through *consistency*. Consistency models [82] enforce a self-consistency mapping $\boldsymbol{f}^{(t)} : \boldsymbol{x}_t \mapsto \boldsymbol{x}_0$ along the probability flow ODE [83, 82], such that all points on ODE trajectory map to a common origin:

$$\boldsymbol{x}_0 = \boldsymbol{f}^{(t)}(\boldsymbol{x}_t) = \boldsymbol{f}^{(t')}(\boldsymbol{x}_{t'}), \quad \forall t, t' \in [0, T]. \tag{5}$$

This property induces few-step generation, as the model is trained to *directly predict the* $\boldsymbol{x}_0$ *sample from any noisy timestep* [102, 22]. Nonetheless, as discussed previously (Section 2.2), directly optimizing using $\boldsymbol{x}_0$-error ($\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2$), while invariant to $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ parameterization, does not enforce or preserve *consistency* across timesteps and thus fails to capture the core inductive bias of FSD models. To address this, we decompose the $\boldsymbol{x}_0$-error along the denoising timestep trajectory:

Proposition 1. *Let* $0 = t_0 < t_1 < \cdots < t_m = t$ *and assume* $\boldsymbol{f}_\theta^{(0)}(\boldsymbol{x}) = \boldsymbol{x}$. *Define* $\delta_\theta(\boldsymbol{x}_{t_j}) := \boldsymbol{f}_\theta^{(t_j)}(\boldsymbol{x}_{t_j}) - \boldsymbol{f}_\theta^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}})$, $j \in \{1, \ldots, m\}$. *Then,*

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0 = \sum_{j=1}^{m} \delta_\theta(\boldsymbol{x}_{t_j}), \quad \|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2 \le \sqrt{m} \left(\sum_{j=1}^{m} \|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2 \right)^{1/2}. \tag{6}$$

Proposition 1 (proof in Appendix C.3) shows that the summed squared stepwise discrepancies provide an upper bound on the reconstruction error: $\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2 \le m \sum_{j=1}^m \|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2$. Minimizing these discrepancies reduces this upper bound while encouraging agreement across timesteps. It does not, by itself, guarantee a monotonic reduction in the actual reconstruction error. However, this motivates a consistency-based surrogate for preference learning.

2.4 Consistency-enforced Preference-driven Unlearning (CePU)

Building on the objective mismatch identified above, we seek a DPO-style preference objective motivated by a decomposition of an auxiliary Gaussian log-likelihood ratio and expressed through local consistency errors. The log-likelihood ratio $l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)$ introduced in Section 2.1, however, is not directly expressed in terms of the step-to-step behavior optimized by distilled few-step models. We therefore connect the DPO reward to this behavior through the sample-space decomposition in **Proposition 1**. Specifically, the proposition below rewrites the log-likelihood exactly as the sum of *timestep-local consistency errors* and *cross-timestep interactions*, providing the basis for a tractable consistency-aware preference objective.

Proposition 2. *Assume the Gaussian clean-sample model* $p_\psi^{(t)}(\boldsymbol{x}_0|\boldsymbol{x}_t) = \mathcal{N}(\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t), \sigma_t^2 \boldsymbol{I})$*, for each* $\psi \in \{\theta, \phi\}$ *(**Assumption** 1, Appendix B), with* $\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon$ *and* $\epsilon \sim \mathcal{N}(\boldsymbol{0}, \boldsymbol{I})$*, and the assumptions of **Proposition** 1 for both* θ *and* ϕ*. Let* $\delta_\psi(\boldsymbol{x}_{t_j}) := \boldsymbol{f}_\psi^{(t_j)}(\boldsymbol{x}_{t_j}) - \boldsymbol{f}_\psi^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}})$*. Then the implicit reward* $l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)$ *decomposes exactly as:*

$$l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t) = -\frac{1}{2\sigma_t^2}\Big[\underbrace{\textstyle\sum_{j=1}^m \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j})}_{\textit{timestep-local}} + \underbrace{2\textstyle\sum_{j<k}\big(\langle\delta_\theta(\boldsymbol{x}_{t_j}), \delta_\theta(\boldsymbol{x}_{t_k})\rangle - \langle\delta_\phi(\boldsymbol{x}_{t_j}), \delta_\phi(\boldsymbol{x}_{t_k})\rangle\big)}_{\textit{cross-timestep interactions}}\Big], \tag{7}$$

where $\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}) = \|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2 - \|\delta_\phi(\boldsymbol{x}_{t_j})\|_2^2$.

Proposition 2 (proof in Appendix C.3) establishes an exact identity under the stated assumptions. However, the cross-timestep term couples increments at different points along the trajectory and cannot be evaluated from a single sampled adjacent transition. We therefore retain only the timestep-local component to construct a local consistency objective. This modeling choice preserves the simplicity of DPO-style training.

We define the resulting consistency-motivated surrogate reward $\tilde{l}_\theta(\boldsymbol{x}_0 \mid \boldsymbol{x}_t)$ as:

$$\tilde{l}_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t) = -c_t \sum_{j=1}^m \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}), \qquad c_t = \tfrac{1}{2\sigma_t^2} > 0. \tag{8}$$

Importantly, $\tilde{l}_\theta$ is a heuristic surrogate rather than an approximation with guaranteed sign or ordering relative to l_θ. The two have the same sign whenever the magnitude of the omitted *cross-timestep* contribution is smaller than that of the *timestep-local* component (Appendix C.3), while the practical validity of this surrogate is evaluated empirically in Section 3. This choice replaces the conventional noise-prediction reward with $\Delta_\theta^{\mathrm{C}}(\cdot)$, which directly measures the model's relative step-to-step consistency against the reference model and therefore aligns preference optimization with *few-step generation dynamics*.

Substituting $\tilde{l}_\theta$ for l_θ in the DPO argument in (1) gives

$$-\log\Big(\mathrm{sig}\Big(\beta\Big(\tilde{l}_\theta(\boldsymbol{x}_0^+ \mid \boldsymbol{x}_t^+) - \tilde{l}_\theta(\boldsymbol{x}_0^- \mid \boldsymbol{x}_t^-)\Big)\Big)\Big) = -\log\Big(\mathrm{sig}\Big(-\beta c_t \textstyle\sum_{j=1}^m \Big(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\Big)\Big)\Big). \tag{9}$$

Furthermore, directly evaluating the complete timestep sum inside $\mathrm{sig}(\cdot)$ would still require constructing the full trajectory. To recover stochastic single-step training, we exploit the convexity of $-\log(\mathrm{sig}(-u))$ and apply Jensen's inequality (Appendix, **Lemma 2**), obtaining the per-step upper bound

$$-\log\Big(\mathrm{sig}\Big(-\beta c_t \textstyle\sum_{j=1}^m \Big(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\Big)\Big)\Big) \le -\frac{1}{m}\textstyle\sum_{j=1}^m \log\Big(\mathrm{sig}\Big(-\beta m c_t \Big(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\Big)\Big)\Big). \tag{10}$$

For a fixed partition, the right-hand side of Eq. ((10)) can be optimized by sampling an increment uniformly rather than evaluating the complete sum. The bound contains the scale mc_t, which may depend on the endpoint and partition. In practice, we replace this scale by a constant absorbed into the tuned parameter β and sample fixed-offset timestep pairs. Thus, the implemented objective is a practical local surrogate, rather than an exact stochastic estimator of the bound under arbitrary timestep sampling. Conditioning both preference samples on the undesirable concept prompt $\boldsymbol{c}^-$ gives:

$$\mathcal{L}_{\texttt{C-DPO}}(\theta) = -\mathbb{E}_{(\boldsymbol{x}_{t_j}^+, \boldsymbol{x}_{t_j}^-, \boldsymbol{c}^-, t_j)}\Big[\log\big(\mathrm{sig}\big(-\beta(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+, \boldsymbol{c}^-) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-, \boldsymbol{c}^-))\big)\big)\Big], \tag{11}$$

where

$$\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}, \boldsymbol{c}) = \|\boldsymbol{f}_\theta^{(t_j)}(\boldsymbol{x}_{t_j}, \boldsymbol{c}) - \boldsymbol{f}_\theta^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}}, \boldsymbol{c})\|_2^2 - \|\boldsymbol{f}_\phi^{(t_j)}(\boldsymbol{x}_{t_j}, \boldsymbol{c}) - \boldsymbol{f}_\phi^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}}, \boldsymbol{c})\|_2^2. \tag{12}$$

Thus, $\mathcal{L}_{\texttt{C-DPO}}$ retains the preference-learning structure of $\mathcal{L}_{\texttt{Diff-DPO}}$ but replaces its noise-prediction-based likelihood proxy with the consistency-based signal $\Delta_\theta^{\mathrm{C}}(\cdot)$. Its effectiveness for unlearning in the evaluated FSD models is supported empirically, including the example in Figure 1C (last row).

Preference-based suppression alone, however, does not explicitly constrain the model on non-target concepts and can therefore alter desirable generations. We address this with a complementary *consistency-based retention* regularizer,

$$\mathcal{L}_{\texttt{RET}}(\theta) = \mathbb{E}_{(\boldsymbol{x}_{t_j}^+, \boldsymbol{c}^+, t_j)}\|\boldsymbol{f}_\theta^{(t_j)}(\boldsymbol{x}_{t_j}^+, \boldsymbol{c}^+) - \boldsymbol{f}_\phi^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}}^+, \boldsymbol{c}^+)\|_2^2, \tag{13}$$

Table 1: Comparing unlearning methods on identity unlearning. The best and second-best results among the **preference-based** methods are highlighted in **maroon** and **navy**, respectively.

which anchors the updated model's few-step prediction on non-target concepts to that of the reference model. Combining targeted preference-driven suppression with this utility-preserving constraint gives the final CePU objective:

$$\mathcal{L}_{\texttt{CePU}}(\theta) = \mathcal{L}_{\texttt{C-DPO}}(\theta) + \lambda \mathcal{L}_{\texttt{RET}}(\theta), \tag{14}$$

where λ controls the utility–unlearning *Pareto* frontier (Section 3.4). While $\mathcal{L}_{\texttt{C-DPO}}$ suppresses undesirable generations through consistency-aware preference optimization, $\mathcal{L}_{\texttt{RET}}$ preserves few-step fidelity on non-target concepts, enabling selective unlearning without unnecessarily degrading model utility. Figure 2B summarizes the overall CePU framework.

In practice, the adjacent states $\boldsymbol{x}_{t_j}$ and $\boldsymbol{x}_{t_{j-1}}$, with $t_{j-1} = t_j - k$, are obtained by forward-noising the same clean sample $\boldsymbol{x}_0$ using a shared noise realization ϵ. This defines a coupled forward-noising path, but the resulting states need not lie on the same probability-flow ODE trajectory. The telescoping decomposition remains algebraically valid; the effectiveness of this pairing as a consistency-inspired training surrogate is evaluated empirically. During optimization, the lower-noise prediction is detached, so gradients flow only through the noisier-step prediction. The detached target is fixed within each update but is recomputed from the current model during training. The preference loss encourages lower consistency error for preferred samples relative to dispreferred samples. Algorithm 1 (Appendix E.2) gives the complete procedure.

2.5 Generating Paired Samples

Following Park *et al.* [66], we construct paired samples $(\boldsymbol{x}_0^+, \boldsymbol{x}_0^-)$ using SDEdit [62] for each FSD model. For each dispreferred concept/prompt $\boldsymbol{c}^-$, we first generate the corresponding dispreferred image $\boldsymbol{x}_0^-$, and obtain its preferred counterpart $\boldsymbol{x}_0^+$ by applying SDEdit at a mid-range noise level t_{edit} characterized by strength $\tau \in (0, 1)$ with the corresponding preferred counterfactual prompt $\boldsymbol{c}^+$ (Figure 2A). This produces in-distribution counterfactual pairs that preserve the global scene structure while selectively modifying concept-specific attributes, serving as supervision for preference-based baselines [89, 66, 54, 63], and CePU. We adopt this standard, fully bootstrapped construction following prior work [66]. Paired dataset generation is orthogonal to our core contributions, and complementary efforts have explored improved preference-pair construction strategies for concept removal [41].

3 Experiments and Observations

SD [74] is a standard benchmark model for text-to-image unlearning methods [31, 51, 87, 66, 93, 92, 29, 68, 32, 99, 46, 49, 84, 42, 50, 60, 58, 52, 101, 94]. We therefore evaluate on SD-based FSD models: DreamShaper-V8-LCM (**DS-V8-LCM**) [5], DreamShaper-V7-LCM (**DS-V7-LCM**) [3], and **SD-Turbo** [10]. We primarily compare against preference-based methods, **DPO** [89], **DUO** [66], **PSO** [63], and **SafetyDPO (AlignGuard)** [54]. We additionally include *non-preference fine-tuning–based* baselines (**ESD** [31], **CA** [51], **FADE** [87]), which directly modify model weights and incorporate utility-preservation objectives analogous to $\mathcal{L}_{\texttt{RET}}$. Furthermore, we evaluate *zero-shot* methods (**UCE** [32], **SAFREE** [99]), which are *training-free* and *timestep-agnostic*, thus applicable to FSD models. For DS-V7-LCM, DS-V8-LCM, and SD-Turbo, we generate evaluation images using four sampling steps with the LCM scheduler [59] and classifier-free guidance disabled. Additional training, paired dataset generation, and evaluation details are provided in Appendix E.

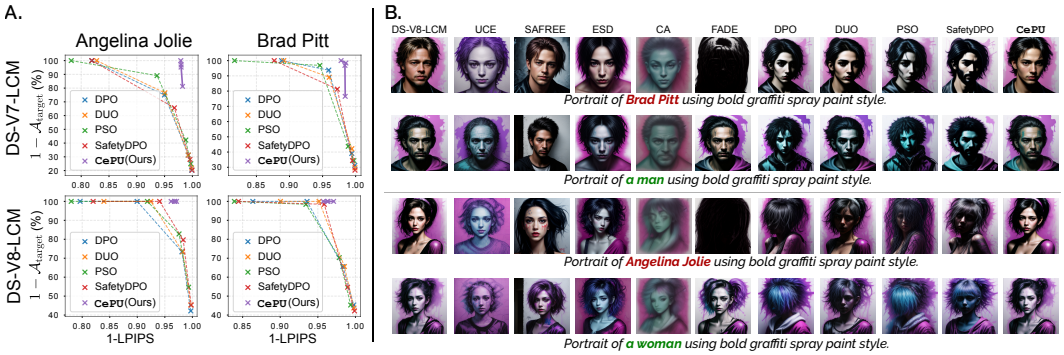

Figure 3: **A.** *Pareto*-curves for $\beta \in \{100, 250, 500, 1000\}$ (left–to-right). Increasing β favors utility retention via stronger alignment to the reference model. We observe a trade-off between target forgetting $1 - \mathcal{A}_{\text{target}} \uparrow$ and generation utility $1 - \text{LPIPS} \uparrow$. CePU is able to attain superior target forgetting with the highest utility. **B.** Qualitative results show effective targeted forgetting while preserving non-target semantics; competing methods often degrade realism or attributes such as pose, hairstyle, and lighting. **See supplementary material for additional visual examples**.

3.1 Identity Unlearning

We evaluate celebrity identity removal on two targets: *Angelina Jolie* and *Brad Pitt* identities. We assess: (i) target identity suppression via target identity accuracy $\mathcal{A}_{\text{target}}$ and non-target identity preservation accuracy $\mathcal{A}_{\text{others}}$ (details in Appendix E.3), using the Giphy celebrity detector [6], and (ii) utility retention via LPIPS [103] between pre- and post-unlearning outputs on the same identity-agnostic prompts with the same seed. We further report the harmonic mean ($\mathcal{H}_{\text{mean}}$) of $(1 - \mathcal{A}_{\text{target}})$ and $\mathcal{A}_{\text{others}}$ to unify the utility–unlearning trade-offs. In Table 1, CePU achieves the highest harmonic mean among the reported preference-based configurations in all four identity settings and the lowest LPIPS in three of the four settings. These results indicate a favorable balance between target suppression and utility preservation. To examine the effect of the consistency-based reward, we sweep β across preference-based methods and compare target suppression against perceptual utility. As shown in Figure 3A, CePU exhibits a favorable empirical unlearning–utility trade-off relative to the evaluated preference-based baselines. Furthermore, in Figure 3B, we qualitatively observe that CePU (last column) demonstrates targeted identity unlearning (first and third row) while preserving non-targeted attributes such as background, lighting, and pose (second and fourth row). Additionally, we direct the readers to Appendix E for prompt construction, training dataset, and evaluation details, and Appendix F.3 for comprehensive results with different β values.

Table 2: NudeNet [9] detections on red-teaming prompts. The best and second-best results among the **preference-based** methods are highlighted in **maroon** and **navy**, respectively.

3.2 Nudity Unlearning

For nudity unlearning, we evaluate using NudeNet detector [9] by counting detections of exposed body parts, reported as Defense Success Rate (**DSR**), *i.e.*, the percentage reduction relative to the original FSD model. Utility is assessed via LPIPS and CLIP score (**CS**) [43] on benign prompts sampled by Yang *et al.* [95]. We benchmark on diverse red-teaming sets such as **I2P** [78], **MMA-A/MMA-S** [95], **RAB** [88], **P4D** [23], **SP** [96] none of which are seen during unlearning. In Table 2, CePU achieves the highest DSR among the reported preference-based configurations on DS-V8-LCM and SD-Turbo. On DS-V8-LCM, FADE achieves a higher DSR but causes substantially greater perceptual deviation. These results highlight the importance of evaluating suppression and utility jointly. Similar to identity unlearning we sweep β values to analyze the DSR-utility trade-off, Figure 4

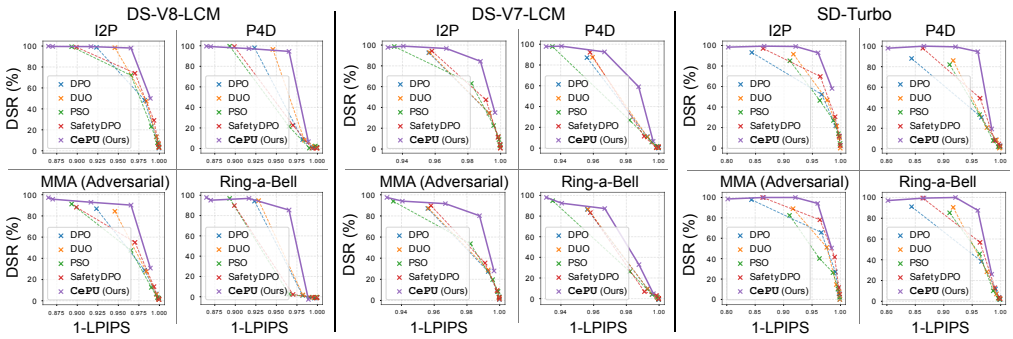

Figure 4: *Pareto*-curves for multiple preference-driven unlearning methods on the nudity-unlearning task for different $\beta \in \{100, 250, 500, 1000, 2000\}$ (left-to-right). Each curve illustrates the trade-off between defense success rate (DSR) ↑ (Y-axis) and generation utility measured as $1 - \text{LPIPS}$ ↑ (X-axis).

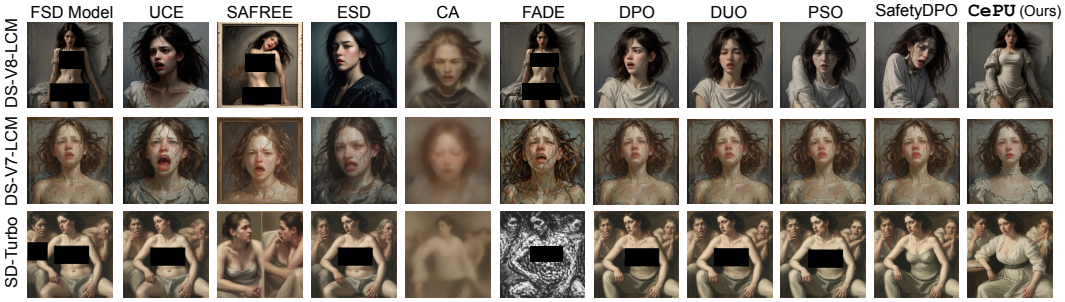

Figure 5: Qualitative comparison of unlearning generations across baseline methods and CePU on DS-V8-LCM [5], DS-V7-LCM [3], and SD-Turbo [10]. CePU is able to *unlearn* the targeted concept while preserving non-targeted semantics (pose, lighting, background, *etc.*). **See supplementary material for additional visual examples**.

shows that CePU again attains a more favorable *Pareto*-frontier between safety (DSR) and utility (LPIPS) showing superior coverage, highlighting the benefit of the proposed consistency-based reward. Qualitative results (Figure 5) further show improved suppression under implicit prompts (that do not mention inappropriate concepts) where baselines often leak unsafe content. We direct the readers to Appendix E.4 for training prompts, dataset, and further evaluation details, and Appendix F.4 for comprehensive results with different β values and DS-V7-LCM [3] model.

3.3 Object-level Unlearning

Beyond identity and nudity removal, we consider object-level unlearning, a standard benchmark in prior works [31, 32, 87]. In contrast to identity-style settings, preference-based objectives are *ill-defined* here: there is no canonical preferred counterpart for a target object, leading to ambiguity. As a result, prior preference-based methods, *e.g.*, DUO [66] and SafetyDPO [54], do not evaluate this setting. To resolve this, we adopt a simple strategy inspired by negative preference optimization (**NPO**) [104], *i.e.*, we omit the positive preference term $\Delta^{\text{C}}_{\theta}(\boldsymbol{x}^{+}_{t_j}, \boldsymbol{c}^{-})$ from $\mathcal{L}_{\texttt{C-DPO}}$, thereby eliminating the need for a preferred concept example. Hence, the resulting objective $\mathcal{L}^{\text{object}}_{\texttt{C-DPO}}$ is defined as:

$$\mathcal{L}^{\text{object}}_{\texttt{C-DPO}}(\theta) = -\mathbb{E}_{(\cancel{\boldsymbol{x}^{+}_{t_j}}, \boldsymbol{x}^{-}_{t_j}, \boldsymbol{c}^{-}, t_j)}\Big[\log\big(\text{sig}\big(-\beta(\cancel{\Delta^{\text{C}}_{\theta}(\boldsymbol{x}^{+}_{t_j}, \boldsymbol{c}^{-})} - \Delta^{\text{C}}_{\theta}(\boldsymbol{x}^{-}_{t_j}, \boldsymbol{c}^{-}))\big)\big)\Big] = -\mathbb{E}_{(\boldsymbol{x}^{-}_{t_j}, \boldsymbol{c}^{-}, t_j)}\Big[\log\big(\text{sig}\big(\beta\Delta^{\text{C}}_{\theta}(\boldsymbol{x}^{-}_{t_j}, \boldsymbol{c}^{-})\big)\big)\Big]. \quad (15)$$

This objective encourages larger relative consistency error $\Delta^{C}_{\theta}(\boldsymbol{x}^{-}_{t_j}, \boldsymbol{c}^{-})$ on target samples. The logistic loss approaches zero as this quantity increases. The retention regularizer separately constrains changes on retained concepts. We keep the consistency-based regularizer $\mathcal{L}_{\texttt{RET}}$ (13) as-is to preserve adjacent concepts. Notably, this formulation *removes the requirement for coupled preference pairs*, allowing $\boldsymbol{x}^{+}$ and $\boldsymbol{x}^{-}$ to be generated *independently* based on the decided retain/unlearn object classes. Following prior work [31, 32, 87, 99, 51], we evaluate on Imagenette [8] class unlearning. We report

Table 3: Object-level unlearning on Imagenette [8] classes. Best and second-best numbers are highlighted in **maroon** and **navy**, respectively.

target object class accuracy $\mathcal{A}_{\text{target}}$, non-target object accuracy $\mathcal{A}_{\text{others}}$, LPIPS on non-target generated samples, and the harmonic mean $\mathcal{H}_{\text{mean}}$ between $1 - \mathcal{A}_{\text{target}}$ and $\mathcal{A}_{\text{others}}$.

As observed in Table 3, `CePU` demonstrates *competitive* performance compared to FADE [87] in $\mathcal{H}_{\text{mean}}$ (75.66 % vs. 74.42 %), while yielding *lower* LPIPS (0.09 vs. 0.12), indicating improved utility preservation. In Appendix F.1, we compare against *preference-based* and *zero-shot* methods. Furthermore, following Thakral *et al.* [87], we also conduct fine-grained category/object unlearning analysis in Appendix F.2. We direct the readers to Appendix E.5 for training prompt construction, dataset and evaluation details.

3.4 Additional Analysis and Observations

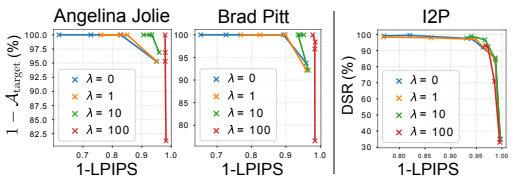

Figure 6: *Pareto*-plots similar to Figures 3 and 4 with different λ values on DS-V7-LCM [3] for identity unlearning (*Angelina Jolie* and *Brad Pitt*), and nudity unlearning (*I2P* prompts).

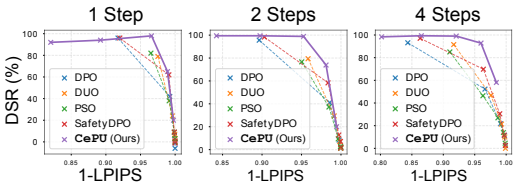

Figure 7: *Pareto*-plots showing the unlearning-utility trade-off, similar to Figure 4 of SD-Turbo [10] on *I2P* prompts for different sampling steps across β sweeps.

Effect of λ and β. `CePU` (14) includes a utility-preservation regularizer weighted by λ. We analyze its effects on *Pareto* curves (Figure 6) for identity and nudity (I2P) unlearning. A clear trade-off emerges: increasing λ improves utility on non-target prompts but weakens unlearning, while smaller λ strengthens unlearning at the cost of utility. For identity unlearning, λ=100 achieves a strong balance (near-perfect UA with minimal degradation), while for nudity, λ=10 yields the best DSR–utility frontier under I2P [78]. Based on this analysis we fixed the λ value for `CePU` in all the experiments. The preference parameter β provides different operating points along the empirical trade-off curve. Larger β generally improves utility retention (Figures 3, 4, 6, and 7).

Number of sampling steps. To assess robustness to the number of sampling steps, we perform an ablation over the number of sampling steps while keeping all other training and evaluation settings fixed. Figure 7 compares the resulting *Pareto* curves for nudity unlearning tasks (I2P prompts). We observe that `CePU` maintains effective unlearning even in the extreme single-step setting, demonstrating a favorable DSR–utility trade-off.

Paired sample generation. We use a fixed SDEdit-generated dataset [62, 66] across all preference-based methods to control variation due to training-pair construction and enable a fair comparison. We use SDEdit to construct counterfactual pairs by perturbing an image to timestep $t_{\text{edit}} = \lfloor \tau T \rfloor$ and denoising it back to $t = 0$, where $\tau \in (0, 1)$ controls the edit strength and T denotes the number of timesteps in the training noise schedule. The process is fully self-bootstrapped, using model-generated samples to mitigate data–model mismatch. We observe that varying τ has only a marginal effect on I2P detections and LPIPS (Figure 8), suggesting robustness over the evaluated range of edit strengths. The computational cost is dominated by denoiser evaluations, with per-pair complexity $\mathcal{O}((T + t_{\text{edit}})\, C_{\text{Denoiser}})$, assuming T evaluations for source-image generation and t_{edit} evaluations for editing. Here, C_{Denoiser} denotes the computational cost of a single denoiser forward pass. Example pairs are provided in Appendix E.1.

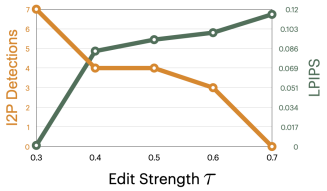

Figure 8: I2P detections vs. LPIPS across edit strengths τ.

Generalization across FSD models. While CePU is motivated by the consistency property (Sections 2.3 and 2.4), its applicability is not restricted to the consistency-model family [82, 59]. Empirically, we observe effective unlearning on SD-Turbo [10], which uses adversarial diffusion distillation [77], combining score distillation and adversarial objectives. We further extend CePU to velocity-parameterized flow-matching models by converting predicted velocities into clean-sample predictions and applying the same consistency-based objective. Experiments on the MMDiT-based SD3-Turbo model [57] demonstrate effective nudity unlearning with a favorable unlearning–retention trade-off at the evaluated operating points. Appendix F.6 provides the derivation and experimental results. Together, these findings support the applicability of our consistency-inspired objective beyond consistency-distilled backbones under the evaluated configurations.

4 Related Works

Unlearning in T2I diffusion models. Unlearning in diffusion models has emerged as an important direction for the responsible deployment of generative systems [42, 60, 58, 52, 101, 94, 18, 17, 91, 40, 24]. Early work such as ESD [31] removes targeted concepts by fine-tuning the U-Net using noise-prediction-based objectives. CA [51] adopts a similar counterfactual fine-tuning strategy, while recently FADE [87] introduces fine-grained unlearning with a prior objective to preserve neighboring concepts. Other directions explore weight-saliency pruning [92, 29, 20], multi-objective optimization for balancing erasure and utility [93, 50, 33], meta-learning for faster concept removal [68, 67, 34, 47], and adversarial methods for robust concept erasure [84, 39, 46, 49, 105, 16]. Complementary works study *zero-shot* unlearning through closed-form weight updates (UCE) [32] or prompt-embedding manipulation (SAFREE) [99]. In our experiments, we evaluate baselines implemented in the *HuggingFace's Diffuser* [2] ecosystem [31, 51, 32, 99, 87]. Methods implemented in the original *CompVis* framework [1], including [92, 29, 68, 46, 49], are not included because adapting their implementations to the evaluated FSD checkpoints was outside the scope of this study.

Preference-based unlearning. DPO [72] learns from ranked output pairs via a Bradley–Terry model [15], avoiding on-policy rollouts. Diffusion-DPO [89] adapts this idea to diffusion models by optimizing preferences in the ϵ-residual space. For unlearning, DUO [66] treats unsafe/safe generations as dispreferred/preferred pairs and introduces a prior-preserving regularizer to maintain utility, while SafetyDPO (AlignGuard) [54] uses prompt-conditioned DPO objectives to jointly suppress targeted concepts and preserve non-targeted quality. However, *these methods have not been evaluated on FSD models, which we study in this work*. PSO [63] extends preference optimization to FSD models; although not designed for unlearning, we adapt it as a baseline. Beyond diffusion, preference-based unlearning has also shown strong results in large language models [104, 28, 26, 56, 53, 61], highlighting its general effectiveness.

Few-step distilled models. FSD diffusion models compress the long sampling trajectory of a base model into only a few steps (2-8) to achieve fast text-to-image generation. Prominent strategies pursue this goal via different mechanisms: LCMs enforce cross-time agreement (*consistency*) in latent space to enable few-step sampling with strong fidelity [59, 82]; *Turbo* variants (*e.g.*, SD-Turbo) couple score-distillation sampling [71] with adversarial losses to sharpen outputs [77, 76]. Distribution-matching distillation aligns the student's output distribution to the teacher using divergence-based objectives [98, 97]. Moreover, recent work on score-matching-based distillation [106, 19, 107] and mean-flows [35] have shown to even surpass the teacher model in terms of image generation quality in few-steps.

5 Conclusion

In this work, we studied post-distillation unlearning for few-step distilled (FSD) text-to-image models. We identified limitations of directly transferring noise-prediction-based preference objectives to the evaluated FSD models. We introduced CePU, a consistency-enforced, preference-driven objective that replaces the conventional noise-prediction proxy with a consistency-inspired surrogate reward. Across the evaluated configurations, CePU achieves favorable empirical trade-offs between targeted suppression and generation utility for identity and nudity unlearning, including evaluation on diverse red-teaming prompts. We also extended the framework to object-level unlearning. Our derivation provides a likelihood-based motivation for local consistency rewards under an auxiliary Gaussian model; the effectiveness of the resulting surrogate is supported empirically.

A Preliminaries

Diffusion Models. Diffusion models (DM) learn a data distribution $p(\boldsymbol{x}_0)$ by reversing a fixed Markovian noising process of length T. The forward process produces $\boldsymbol{x}_t \sim q(\boldsymbol{x}_t \mid \boldsymbol{x}_0) = \mathcal{N}\big(\sqrt{\alpha_t}\,\boldsymbol{x}_0,\,(1-\alpha_t)\boldsymbol{I}\big)$ with a decreasing schedule $\alpha_{1,\dots,T} \in (0,1]$ [81]. For our discussion, we follow the notation conventions adopted by [81]. A standard training objective with noise-prediction parameterization is

$$\mathcal{L}_{\mathrm{DM}}(\theta) = \mathbb{E}_{\boldsymbol{x}_0\sim p_{\mathrm{data}},\, t\sim\mathcal{U}\{1,\dots,T\},\, \epsilon\sim\mathcal{N}(\mathbf{0},\boldsymbol{I})}\left[\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2\right], \tag{16}$$
$$\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon.$$

Consistency Models. The Consistency Model (CM) [82, 59] is a generative framework designed for one-step or few-step sampling. Its central idea is to learn a consistency function that maps any point on the probability flow ODE (PF-ODE) trajectory to its origin, *i.e.*, $\boldsymbol{f}^{(t)} : \boldsymbol{x}_t \mapsto \boldsymbol{x}_0$. A defining property of this function is self-consistency; that is, any two points $\boldsymbol{x}_t$ and $\boldsymbol{x}_s$ on the same PF-ODE trajectory [83, 82] must map to the same origin:

$$\boldsymbol{x}_0 = \boldsymbol{f}^{(t)}(\boldsymbol{x}_t) = \boldsymbol{f}^{(s)}(\boldsymbol{x}_s), \forall t, s \in (0, T]. \tag{17}$$

The output of a CM/LCM $\boldsymbol{f}_\theta^{(t)}$, θ denoting the consistency model weights, is typically parameterized using skip connections [12, 48] as:

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = c_{\text{skip}}(t)\boldsymbol{x}_t + c_{\text{out}}(t)\boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t), \tag{18}$$

where $c_{\text{skip}}(0) = 1$ and $c_{\text{out}}(0) = 0$ ensure that $\boldsymbol{f}_\theta^{(0)}(\boldsymbol{x}_0) = \boldsymbol{x}_0$. Here, $\boldsymbol{F}_\theta$ denotes the approximation of $\boldsymbol{x}_0$ at time step t, defined as:

$$\boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\cdot\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} \quad (\epsilon\text{-prediction}), \tag{19}$$

CM/LCMs can be obtained either by distilling a standard diffusion model into a few-step equivalent via *consistency distillation*, or by training a model from scratch using *consistency learning*.

In the distillation setting, an ODE solver Ψ (typically a DDIM sampler [81]) provides a one-step denoised estimate $\hat{\boldsymbol{x}}_{t-k}^{\Psi}$ of the noisy sample $\boldsymbol{x}_t \sim q(\boldsymbol{x}_t|\boldsymbol{x}_0)$, using the teacher's predicted score. Consistency distillation is then enforced by aligning outputs across steps:

$$\mathcal{L}_{\mathrm{CD}}(\theta) = \mathbb{E}_{\boldsymbol{x}_t,t}\big[d\big(\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t), \boldsymbol{f}_{\theta^-}^{(t-k)}(\hat{\boldsymbol{x}}_{t-k}^{\Psi})\big)\big], \forall k \le t < T \tag{20}$$

where θ^- denotes the EMA (or frozen) parameters of θ, and $d(\cdot,\cdot)$ is typically the ℓ_2 squared or Huber distance [59, 82, 25]. The stride $k \ge 1$ specifies the time-step gap used for alignment. Similarly, a CM/LCM can also be trained directly, without a teacher, by enforcing consistency between two noisy samples $\boldsymbol{x}_t$ and $\boldsymbol{x}_{t-k}$ from the same initialized $\boldsymbol{x}_0$ by minimizing $\mathcal{L}_{\mathrm{CT}}(\theta)$ given by:

$$\mathcal{L}_{\mathrm{CT}}(\theta) = \mathbb{E}_{\boldsymbol{x}_0,t,\epsilon}\left[d\Big(\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t), \boldsymbol{f}_{\theta^-}^{(t-k)}(\boldsymbol{x}_{t-k})\Big)\right], \tag{21}$$

both $\boldsymbol{x}_t$ and $\boldsymbol{x}_{t-k}$ are formed from the same $\boldsymbol{x}_0$ and ϵ using their respective forward-noising coefficients.

B Probabilistic Sampling Framework for Diffusion Models

In diffusion-style generative modeling, the generative process is constructed as an approximation to the reverse of an inference (forward) process. Classical formulations assume a Markovian forward process, but this restriction is unnecessary: what matters is that the forward marginals $q(\boldsymbol{x}_t|\boldsymbol{x}_0)$ [81] are preserved, since the diffusion's learning objectives (16), (20), and (21) do not depend on the joint $q(\boldsymbol{x}_{1:T}|\boldsymbol{x}_0)$ [81] . Thus, one can construct non-Markovian inference distributions that share the same marginals while admitting richer sampling.

We first demonstrate that Diffusion samplers (*e.g.*, **DDPM** [44], **DDIM**, [81]) and few-step samplers (*e.g.*, **LCM** [59]) are instances of a single reverse process induced by a non-Markovian forward family that preserves the same marginals [81]. Demonstrated in **Lemma 3**

Building on **Lemma 3**, which defines the non-Markovian inference distribution $q_\sigma(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t, \boldsymbol{x}_0)$, a trainable generative process $p_\theta(\boldsymbol{x}_{0:T}) = p_\theta(\boldsymbol{x}_T) \prod_{t=1}^{T} p_\theta^{(t)}(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t)$ is defined to replace the intractable true $\boldsymbol{x}_0$. Intuitively, given a noisy input $\boldsymbol{x}_t$, the network predicts the underlying clean signal $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ (an approximation of $\boldsymbol{x}_0$), which is then injected into the reverse conditional in **Lemma 3** (36) to yield a sample $\boldsymbol{x}_{t-1}$. The overall process is defined with prior $p_\theta(\boldsymbol{x}_T) = \mathcal{N}(\mathbf{0}, \boldsymbol{I})$ and transitions

$$p_\theta^{(t)}(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t) = \begin{cases} \mathcal{N}\big(\boldsymbol{f}_\theta^{(1)}(\boldsymbol{x}_1),\, \sigma_1^2 \boldsymbol{I}\big), & t = 1, \\ q_\sigma\big(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t,\, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big), & t > 1, \end{cases} \tag{22}$$

so that the generative process mirrors the structure of the non-Markovian inference family while remaining fully tractable. Gaussian noise at the final step (t=1) is added to provide support at all time steps. Hence, one obtains $\boldsymbol{x}_{t-1}$ from $\boldsymbol{x}_t$ via

$$\boldsymbol{x}_{t-1} \;=\; \boldsymbol{\mu}_\sigma^{(t)}\Big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\Big) \;+\; \sigma_t\, \epsilon_t, \quad \epsilon_t \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}). \tag{23}$$

All notations here follow Lemma 1 (Appendix B) of Song *et al.* [81].

Accelerated sampling. The reverse process in (23) need not be evaluated at every diffusion time step. Since the learning objective depends only on the marginal distributions $q(\boldsymbol{x}_t \mid \boldsymbol{x}_0)$, rather than on a particular factorization of the forward process, we may define the inference process over a subsequence of time indices

$$\boldsymbol{\tau} = \{\tau_1, \tau_2, \ldots, \tau_S\}, \qquad 1 \le \tau_1 < \tau_2 < \cdots < \tau_S \le T, \qquad S \ll T, \tag{24}$$

while preserving the same marginals

$$q(\boldsymbol{x}_{\tau_i} \mid \boldsymbol{x}_0) = \mathcal{N}\big(\sqrt{\alpha_{\tau_i}}\boldsymbol{x}_0,\, (1 - \alpha_{\tau_i})\boldsymbol{I}\big)\,. \tag{25}$$

The corresponding generative process follows the reversed sampling trajectory $\tau_S \to \tau_{S-1} \to \cdots \to \tau_1 \to 0$, rather than traversing all T diffusion steps.

For two consecutive elements $\tau_{i-1} < \tau_i$ of the sampling trajectory, the generalized reverse update can be written as

$$\begin{aligned} \boldsymbol{x}_{\tau_{i-1}} = {} & \sqrt{\alpha_{\tau_{i-1}}}\, \boldsymbol{f}_\theta^{(\tau_i)}(\boldsymbol{x}_{\tau_i}) \\ & + \sqrt{1 - \alpha_{\tau_{i-1}} - \sigma_{\tau_i}^2}\, \left(\frac{\boldsymbol{x}_{\tau_i} - \sqrt{\alpha_{\tau_i}}\, \boldsymbol{f}_\theta^{(\tau_i)}(\boldsymbol{x}_{\tau_i})}{\sqrt{1 - \alpha_{\tau_i}}} \right) + \sigma_{\tau_i} \epsilon_i, \qquad \epsilon_i \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}). \end{aligned} \tag{26}$$

Clean-sample conditional (modeling assumption). The reverse transitions in (22) and (26) specify how samples are generated; they do not by themselves define a clean-sample conditional $p_\theta(\boldsymbol{x}_0 \mid \boldsymbol{x}_t)$ for an arbitrary t. Following the accelerated variational formulation of DDIM ([81], Appendix C.1), for a sampling subsequence $\boldsymbol{\tau}$ with $\tau_S = T$ and $\bar{\boldsymbol{\tau}} = \{1, \ldots, T\} \setminus \boldsymbol{\tau}$, the generative model is augmented as

$$p_\theta(\boldsymbol{x}_{0:T}) \coloneqq p_\theta(\boldsymbol{x}_T) \underbrace{\prod_{i=1}^{S} p_\theta^{(\tau_i)}(\boldsymbol{x}_{\tau_{i-1}} \mid \boldsymbol{x}_{\tau_i})}_{\text{transitions used for sampling}} \times \underbrace{\prod_{t \in \bar{\boldsymbol{\tau}}} p_\theta^{(t)}(\boldsymbol{x}_0 \mid \boldsymbol{x}_t)}_{\text{conditionals used in the variational objective}}, \tag{27}$$

where $p_\theta^{(\tau_i)}(\boldsymbol{x}_{\tau_{i-1}} \mid \boldsymbol{x}_{\tau_i}) = q_\sigma\big(\boldsymbol{x}_{\tau_{i-1}} \mid \boldsymbol{x}_{\tau_i}, \boldsymbol{f}_\theta^{(\tau_i)}(\boldsymbol{x}_{\tau_i})\big)$ for $i \in [S]$, $i > 1$, and $p_\theta^{(t)}(\boldsymbol{x}_0 \mid \boldsymbol{x}_t) = \mathcal{N}\big(\boldsymbol{x}_0; \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t), \sigma_t^2 \boldsymbol{I}\big)$ otherwise ([81], Eqs. 56–57). The clean-sample conditional is thus a separately specified component of the variational model, rather than a conditional obtained by marginalizing or rearranging the reverse sampler.

We adopt the same construction:

Assumption 1 (Gaussian clean-sample conditional)**.** *For every timestep t and model $\psi \in \{\theta, \phi\}$, $p_\psi^{(t)}(\boldsymbol{x}_0 \mid \boldsymbol{x}_t) \coloneqq \mathcal{N}\big(\boldsymbol{x}_0; \boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t), \sigma_t^2 \boldsymbol{I}\big)$, where $\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t)$ is the model's clean-sample prediction and $\sigma_t^2 > 0$ is fixed and shared by θ and ϕ.*

We retain the variance notation σ_t^2 used in DDIM [81]. The Gaussian likelihood-ratio derivation assumes $\sigma_t^2 > 0$, with the same variance for the trainable and reference models. The deterministic sampling case $\sigma_t = 0$ is considered separately and is not substituted into the positive-variance likelihood-ratio expressions.

This is the same modeling choice that Diffusion-DPO uses to derive its objective ([89], Supp. S.4). An isotropic Gaussian with fixed variance is a coarse approximation of the true clean-sample posterior, which is in general non-Gaussian and multimodal. We adopt it only to obtain a tractable likelihood-ratio reward, and all results that depend on it (Lemma 4 and Proposition 2) are stated conditionally on Assumption 1.

C Proofs

C.1 Lemmas

Lemma 1. *Given $\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon$ with $\epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})$ and the PMP parameterization $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = (\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t))/\sqrt{\alpha_t}$, we have*

$$\left\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\right\|_2^2 = \tfrac{1-\alpha_t}{\alpha_t}\left\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\right\|_2^2, \tag{28}$$

yielding identical descent directions up to a scalar.

Proof. Using the given parameterization and forward marginal,

$$\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \boldsymbol{x}_0 - \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} = \frac{\sqrt{\alpha_t}\boldsymbol{x}_0 - \boldsymbol{x}_t + \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} \tag{29}$$

$$= \frac{\sqrt{\alpha_t}\boldsymbol{x}_0 - (\sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon) + \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} \tag{30}$$

$$= \frac{-\sqrt{1-\alpha_t}\epsilon + \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} \tag{31}$$

$$= \sqrt{\frac{1-\alpha_t}{\alpha_t}}\left(\epsilon_\theta^{(t)}(\boldsymbol{x}_t) - \epsilon\right). \tag{32}$$

Taking squared Euclidean norms yields

$$\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2 = \frac{1-\alpha_t}{\alpha_t}\|\epsilon_\theta^{(t)}(\boldsymbol{x}_t) - \epsilon\|_2^2 \tag{33}$$

□

Lemma 2. *Let $f(u) := -\log(\mathrm{sig}(-u)) = \log(1+e^u)$ be the softplus. Then f is increasing and strictly convex on $\mathbb{R}$. Consequently, for any $u_1, \ldots, u_m \in \mathbb{R}$,*

$$f\left(\sum_{j=1}^m u_j\right) = f\left(\frac{1}{m}\sum_{j=1}^m m u_j\right) \;\le\; \frac{1}{m}\sum_{j=1}^m f(m u_j), \tag{34}$$

with equality if and only if $u_1 = \cdots = u_m$.

Proof. First, $f'(u) = \frac{e^u}{1+e^u} = \mathrm{sig}(u) \in (0,1)$ for all u, hence f is (strictly) increasing. Next,

$$f''(u) \;=\; \mathrm{sig}(u)\big(1-\mathrm{sig}(u)\big) \;>\; 0 \quad \text{for all } u \in \mathbb{R},$$

so f is strictly convex. Define the convex function $g(v) := f(mv)$. By Jensen's inequality,

$$f\left(\sum_{j=1}^m u_j\right) = g\left(\frac{1}{m}\sum_{j=1}^m u_j\right) \;\le\; \frac{1}{m}\sum_{j=1}^m g(u_j) = \frac{1}{m}\sum_{j=1}^m f(m u_j),$$

which is (34). Since g is strictly convex, equality holds iff $u_1 = \cdots = u_m$. □

Lemma 3 (Non-Markovian forward processes [81])**.** *Consider a family of inference distributions indexed by $\sigma \in \mathbb{R}^T_{\geq 0}$, with $0 \leq \sigma_t^2 \leq 1 - \alpha_{t-1}$ for $t > 1$:*

$$q_\sigma(\boldsymbol{x}_{1:T} \mid \boldsymbol{x}_0) := q_\sigma(\boldsymbol{x}_T \mid \boldsymbol{x}_0) \prod_{t=2}^{T} q_\sigma(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t, \boldsymbol{x}_0). \tag{35}$$

Here, $q_\sigma(\boldsymbol{x}_T \mid \boldsymbol{x}_0) = \mathcal{N}(\sqrt{\alpha_T}\,\boldsymbol{x}_0, (1-\alpha_T)\boldsymbol{I})$, and for all $t > 1$ we have

$$q_\sigma(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t, \boldsymbol{x}_0) = \mathcal{N}\big(\boldsymbol{\mu}_\sigma^{(t)}(\boldsymbol{x}_t, \boldsymbol{x}_0),\ \sigma_t^2 \boldsymbol{I}\big), \tag{36}$$

where the mean is given by

$$\boldsymbol{\mu}_\sigma^{(t)}(\boldsymbol{x}_t, \boldsymbol{x}_0) = \sqrt{\alpha_{t-1}}\,\boldsymbol{x}_0 + \sqrt{1 - \alpha_{t-1} - \sigma_t^2}\ \frac{\boldsymbol{x}_t - \sqrt{\alpha_t}\,\boldsymbol{x}_0}{\sqrt{1-\alpha_t}}. \tag{37}$$

This construction ensures that the resulting joint inference distribution has the desired marginals, i.e.*, $q_\sigma(\boldsymbol{x}_t|\boldsymbol{x}_0) = \mathcal{N}(\sqrt{\alpha_t}\,\boldsymbol{x}_0, (1-\alpha_t)\boldsymbol{I})$ for all t.*

Proof. Please refer to Lemma 1 (Appendix B) of [81]. □

Lemma 4. *Under **Assumption 1**, let $\boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\,\epsilon$, $\epsilon \sim \mathcal{N}(\boldsymbol{0}, \boldsymbol{I})$, and let $\boldsymbol{f}_{\{\theta,\phi\}}^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_{\{\theta,\phi\}}^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}$ (PMP parameterization). Then the implicit reward $l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t) = \log\left(\frac{p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)}{p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t)}\right)$ satisfies the exact identity*

$$\log\left(\frac{p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)}{p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t)}\right) = -w_t\Big(\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2 - \|\epsilon - \epsilon_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2\Big), \qquad w_t := \frac{1-\alpha_t}{2\alpha_t\sigma_t^2} > 0. \tag{38}$$

Proof. Write the two Gaussian densities with equal covariance:

$$p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t) = \mathcal{N}\big(\boldsymbol{x}_0; \mu_\theta, \sigma_t^2\boldsymbol{I}\big), \qquad p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t) = \mathcal{N}\big(\boldsymbol{x}_0; \mu_\phi, \sigma_t^2\boldsymbol{I}\big),$$

with $\mu_\theta = \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ and $\mu_\phi = \boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t)$. The Gaussian log-density is

$$\log p(\boldsymbol{x}_0|\boldsymbol{x}_t) = -\frac{d}{2}\log(2\pi) - \frac{d}{2}\log(\sigma_t^2) - \frac{1}{2\sigma_t^2}\|\boldsymbol{x}_0 - \mu\|_2^2,$$

so the constant terms cancel in the log-ratio, giving

$$\log\left(\frac{p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)}{p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t)}\right) = -\frac{1}{2\sigma_t^2}\Big(\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2 - \|\boldsymbol{x}_0 - \boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2\Big). \tag{39}$$

Using $\|\boldsymbol{x}_0 - \mu\|_2^2 = \|\mu - \boldsymbol{x}_0\|_2^2$, we can rewrite this as

$$\log\left(\frac{p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)}{p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t)}\right) = \frac{1}{2\sigma_t^2}\Big(\|\boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0\|_2^2 - \|\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0\|_2^2\Big). \tag{40}$$

Furthermore, to express this in terms of the noise-prediction errors, substitute the parameterization of $\boldsymbol{f}_\theta^{(t)}$:

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}, \boldsymbol{x}_t = \sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon. \tag{41}$$

Then

$$\begin{aligned}
\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0 &= \frac{\sqrt{\alpha_t}\boldsymbol{x}_0 + \sqrt{1-\alpha_t}\epsilon - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} - \boldsymbol{x}_0 \\
&= \boldsymbol{x}_0 + \sqrt{\frac{1-\alpha_t}{\alpha_t}}\big(\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\big) - \boldsymbol{x}_0 \\
&= \sqrt{\frac{1-\alpha_t}{\alpha_t}}\big(\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\big).
\end{aligned}$$

Hence

$$\|\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0\|_2^2 = \frac{1-\alpha_t}{\alpha_t}\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2, \tag{42}$$

and analogously,

$$\|\boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0\|_2^2 = \frac{1-\alpha_t}{\alpha_t}\|\epsilon - \epsilon_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2.$$

Plugging these into (40) yields

$$\begin{aligned}\log\left(\frac{p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)}{p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t)}\right) &= \frac{1-\alpha_t}{2\alpha_t\sigma_t^2}\left(\|\epsilon - \epsilon_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2 - \|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2\right)\\ &= -w_t\Big(\|\epsilon - \epsilon_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2 - \|\epsilon - \epsilon_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2\Big),\end{aligned}$$

which is (38). The identity is exact under Assumption 1. The weight $w_t > 0$ depends only on the timestep and not on θ, so it rescales the reward without changing its sign. Diffusion-DPO [89] arrives at an analogous timestep weighting and sets it to a constant in practice. Doing the same here and absorbing the constant into β when substituting (38) into (1) yields the Diffusion-DPO objective (2). This step replaces the timestep-dependent effective temperature βw_t by a constant; it changes the per-timestep scale of the preference logit, but not its sign.

Finally, the Gaussian form of $p_{\psi\in\{\theta,\phi\}}(\boldsymbol{x}_0|\boldsymbol{x}_t)$ is the modeling assumption stated in Assumption 1; it is not implied by the reverse sampling transitions (22) (Appendix B). □

C.2 Corollaries

Corollary 1 (Per-timestep Jensen upper bound)**.** *For any $\beta > 0$, integer $m \geq 1$, and $c_t > 0$, define*

$$u_j \;=\; \beta c_t\,\left(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\right).$$

Then

$$-\log\left(\mathrm{sig}\left(-\textstyle\sum_{j=1}^m \beta c_t\,\left(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\right)\right)\right) \leq \tfrac{1}{m}\textstyle\sum_{j=1}^m\left[-\log\left(\mathrm{sig}\left(-\beta m c_t\left(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\right)\right)\right)\right]. \tag{43}$$

*Equality holds iff the u_j are all equal (*i.e.*, the per-step consistency gaps are uniform across j).*

Proof. Let $f(u) = -\log\mathrm{sig}(-u)$. The left-hand side of (43) is $f\big(\sum_{j=1}^m u_j\big)$ by the definition of u_j. Apply Lemma 2 to obtain

$$f\Big(\sum_{j=1}^m u_j\Big) \;\leq\; \frac{1}{m}\sum_{j=1}^m f(mu_j) = \frac{1}{m}\sum_{j=1}^m\Big[-\log\mathrm{sig}\Big(-mu_j\Big)\Big], \tag{44}$$

and substitute $mu_j = \beta m c_t\big(\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^+) - \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}^-)\big)$ to obtain (43). The equality condition follows from the strict convexity in Lemma 2. □

Corollary 2 (Emergence of samplers)**.** *Let $q_\sigma(\boldsymbol{x}_{1:T} \mid \boldsymbol{x}_0)$ be the non-Markovian forward family of **Lemma 3** with $q_\sigma(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t, \boldsymbol{x}_0) = \mathcal{N}\big(\boldsymbol{\mu}_\sigma^{(t)}(\boldsymbol{x}_t, \boldsymbol{x}_0),\, \sigma_t^2\boldsymbol{I}\big)$, and define the trainable reverse chain as in (22):*

$$p_\theta^{(t)}(\boldsymbol{x}_{t-1} \mid \boldsymbol{x}_t) = \mathcal{N}\Big(\boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big),\, \sigma_t^2\boldsymbol{I}\Big), \quad p_\theta(\boldsymbol{x}_T) = \mathcal{N}(\boldsymbol{0}, \boldsymbol{I}). \tag{45}$$

Then sampling is given by

$$\boldsymbol{x}_{t-1} = \boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) + \sigma_t\,\epsilon, \qquad \epsilon \sim \mathcal{N}(\boldsymbol{0}, \boldsymbol{I}), \tag{46}$$

with

$$\boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) = \sqrt{\alpha_{t-1}}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) + \sqrt{1-\alpha_{t-1}-\sigma_t^2}\,\frac{\boldsymbol{x}_t - \sqrt{\alpha_t}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{1-\alpha_t}} \tag{47}$$

and the following classical samplers are recovered as special cases by appropriate choices of $\{\sigma_t\}$ and the induced *$\boldsymbol{f}_\theta^{(t)}$:*

1. ***DDPM (ancestral) [44].***

   Choose

$$\sigma_t = \sqrt{\frac{1-\alpha_{t-1}}{1-\alpha_t}}\sqrt{1-\frac{\alpha_t}{\alpha_{t-1}}}, \tag{48}$$

   and let $\boldsymbol{f}_\theta^{(t)}$ *be induced by an* ϵ*-prediction head* $\epsilon_\theta^{(t)}(\boldsymbol{x}_t)$ *via*

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}. \tag{49}$$

   Then (46) equals the classical DDPM ancestral update.

2. ***DDIM (deterministic) [81].***

   Set $\sigma_t = 0$ *and keep the same induced* $\boldsymbol{f}_\theta^{(t)}$ *as above (from* ϵ*-prediction). Then (46) yields the deterministic DDIM step.*

3. ***LCM / Consistency schedule (few-step distilled) [59].***

   Set $\sigma_t = \sqrt{1-\alpha_{t-1}}$ *and parameterize* $\boldsymbol{f}_\theta^{(t)}$ *directly in data space (consistency-style) by an affine head*

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = c_{\text{skip}}(t)\,\boldsymbol{x}_t + c_{\text{out}}(t)\,\boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t), \tag{50}$$

   for timestep-dependent scalars $c_{\text{skip}}(t), c_{\text{out}}(t)$ *and network output* $\boldsymbol{F}_\theta^{(t)}$*. Then (46) reduces to the latent consistency / LCM scheduler used for few-step distilled models.*

Proof. Starting from (36) and substituting $\boldsymbol{x}_0 \leftarrow \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ to obtain the mean of the reverse kernel, yielding (46). Given,

1. **DDPM.** Substituting $\sigma_t = \sqrt{\frac{1-\alpha_{t-1}}{1-\alpha_t}}\sqrt{1-\frac{\alpha_t}{\alpha_{t-1}}}$, and $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}$ and $\frac{\boldsymbol{x}_t - \sqrt{\alpha_t}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{1-\alpha_t}} = \epsilon_\theta^{(t)}(\boldsymbol{x}_t)$.

$$\boldsymbol{x}_{t-1} = \boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) + \sigma_t\,\epsilon, \qquad \epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}), \tag{51}$$

Set $\sigma_t = \sqrt{\frac{1-\alpha_{t-1}}{1-\alpha_t}}\sqrt{1-\frac{\alpha_t}{\alpha_{t-1}}}$,

$$\sigma_t = \sqrt{\frac{1-\alpha_{t-1}}{1-\alpha_t}}\sqrt{1-\frac{\alpha_t}{\alpha_{t-1}}} \quad\Longrightarrow\quad \sigma_t^2 = \frac{(1-\alpha_{t-1})(\alpha_{t-1}-\alpha_t)}{\alpha_{t-1}(1-\alpha_t)}. \tag{52}$$

$$\begin{aligned}
1-\alpha_{t-1}-\sigma_t^2 &= (1-\alpha_{t-1}) - \frac{(1-\alpha_{t-1})(\alpha_{t-1}-\alpha_t)}{\alpha_{t-1}(1-\alpha_t)} \\
&= (1-\alpha_{t-1})\left[1 - \frac{\alpha_{t-1}-\alpha_t}{\alpha_{t-1}(1-\alpha_t)}\right] \\
&= (1-\alpha_{t-1})\frac{\alpha_{t-1}(1-\alpha_t) - (\alpha_{t-1}-\alpha_t)}{\alpha_{t-1}(1-\alpha_t)} \\
&= (1-\alpha_{t-1})\frac{\alpha_t(1-\alpha_{t-1})}{\alpha_{t-1}(1-\alpha_t)} \\
&= \frac{\alpha_t(1-\alpha_{t-1})^2}{\alpha_{t-1}(1-\alpha_t)}, \\
\Longrightarrow \sqrt{1-\alpha_{t-1}-\sigma_t^2} &= \frac{(1-\alpha_{t-1})\sqrt{\alpha_t}}{\sqrt{\alpha_{t-1}}\sqrt{1-\alpha_t}}.
\end{aligned} \tag{53}$$

Substituting $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}$

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} \quad \Longrightarrow \quad \sqrt{\alpha_{t-1}}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t - \sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t). \tag{54}$$

Now,

$$\begin{aligned}\boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) &= \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t - \sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t) + \frac{(1-\alpha_{t-1})\sqrt{\alpha_t}}{\sqrt{\alpha_{t-1}}\sqrt{1-\alpha_t}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t) \\ &= \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t + \left(-\sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}} + \frac{(1-\alpha_{t-1})\sqrt{\alpha_t}}{\sqrt{\alpha_{t-1}}\sqrt{1-\alpha_t}}\right)\epsilon_\theta^{(t)}(\boldsymbol{x}_t).\end{aligned} \tag{55}$$

$$\begin{aligned}-\sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}} + \frac{(1-\alpha_{t-1})\sqrt{\alpha_t}}{\sqrt{\alpha_{t-1}}\sqrt{1-\alpha_t}} &= -\frac{\alpha_{t-1}(1-\alpha_t)}{\sqrt{\alpha_{t-1}\alpha_t(1-\alpha_t)}} + \frac{(1-\alpha_{t-1})\alpha_t}{\sqrt{\alpha_{t-1}\alpha_t(1-\alpha_t)}} \\ &= \frac{\alpha_t - \alpha_{t-1}}{\sqrt{\alpha_{t-1}\alpha_t(1-\alpha_t)}}.\end{aligned} \tag{56}$$

Therefore,

$$\boxed{\boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) = \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t + \frac{\alpha_t - \alpha_{t-1}}{\sqrt{\alpha_{t-1}\alpha_t(1-\alpha_t)}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t).} \tag{57}$$

Finally, keeping the chosen σ_t explicit in the update:

$$\boxed{\boldsymbol{x}_{t-1} = \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t + \frac{\alpha_t - \alpha_{t-1}}{\sqrt{\alpha_{t-1}\alpha_t(1-\alpha_t)}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t) + \sqrt{\frac{(1-\alpha_{t-1})(\alpha_{t-1}-\alpha_t)}{\alpha_{t-1}(1-\alpha_t)}}\,\epsilon, \quad \epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}).} \tag{58}$$

2. **DDIM**. Substituting $\sigma_t = 0$ and $\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \boldsymbol{F}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}}$ and $\frac{\boldsymbol{x}_t - \sqrt{\alpha_t}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{1-\alpha_t}} = \epsilon_\theta^{(t)}(\boldsymbol{x}_t)$.

$$\boldsymbol{x}_{t-1} = \boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) + \sigma_t\,\epsilon, \qquad \epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}), \tag{59}$$

Set $\sigma_t = 0$.

$$\sigma_t = 0 \implies \sigma_t^2 = 0, \qquad \sqrt{1-\alpha_{t-1}-\sigma_t^2} = \sqrt{1-\alpha_{t-1}}\,. \tag{60}$$

Hence the update becomes deterministic:

$$\boldsymbol{x}_{t-1} = \sqrt{\alpha_{t-1}}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) + \sqrt{1-\alpha_{t-1}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t). \tag{61}$$

Substitute $\boldsymbol{f}_\theta^{(t)}$.

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \frac{\boldsymbol{x}_t - \sqrt{1-\alpha_t}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t)}{\sqrt{\alpha_t}} \quad \Longrightarrow \quad \sqrt{\alpha_{t-1}}\,\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) = \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t - \sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t).$$

Combine terms.

$$\begin{aligned}\boldsymbol{x}_{t-1} &= \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t - \sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t) + \sqrt{1-\alpha_{t-1}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t) \\ &= \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t + \left(\sqrt{1-\alpha_{t-1}} - \sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}}\right)\epsilon_\theta^{(t)}(\boldsymbol{x}_t).\end{aligned}$$

Optional symmetric form of the coefficient.

$$\sqrt{1-\alpha_{t-1}} - \sqrt{\frac{\alpha_{t-1}(1-\alpha_t)}{\alpha_t}} = \frac{\sqrt{\alpha_t(1-\alpha_{t-1})} - \sqrt{\alpha_{t-1}(1-\alpha_t)}}{\sqrt{\alpha_t}}.$$

Final expression (deterministic DDIM-style step).

$$\boxed{\boldsymbol{x}_{t-1} = \sqrt{\frac{\alpha_{t-1}}{\alpha_t}}\,\boldsymbol{x}_t + \frac{\sqrt{\alpha_t(1-\alpha_{t-1})} - \sqrt{\alpha_{t-1}(1-\alpha_t)}}{\sqrt{\alpha_t}}\,\epsilon_\theta^{(t)}(\boldsymbol{x}_t).} \tag{62}$$

3. **LCM Sampler**

Setting $\sigma_t = \sqrt{1-\alpha_{t-1}}$ makes the residual coefficient in the mean vanish.

$$1-\alpha_{t-1}-\sigma_t^2 \;=\; 1-\alpha_{t-1}-(1-\alpha_{t-1}) \;=\; 0 \quad\Longrightarrow\quad \sqrt{1-\alpha_{t-1}-\sigma_t^2} \;=\; 0.$$

Hence the mean simplifies to

$$\boldsymbol{\mu}_\sigma^{(t)}\big(\boldsymbol{x}_t, \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\big) = \sqrt{\alpha_{t-1}}\;\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t).$$

Final sampling update (keep $\boldsymbol{f}_\theta^{(t)}$ in its own form). Including the chosen σ_t in the transition:

$$\boxed{\boldsymbol{x}_{t-1} = \sqrt{\alpha_{t-1}}\;\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) + \sqrt{1-\alpha_{t-1}}\;\epsilon, \qquad \epsilon \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}).} \tag{63}$$

for LCM, $\boldsymbol{f}_\theta^{(t)}$ is taken as a direct $\boldsymbol{x}_0$-prediction with a consistency parametrization. □

C.3 Propositions

Proposition 1. *Let* $0 = t_0 < t_1 < \cdots < t_m = t$ *and assume* $\boldsymbol{f}_\theta^{(0)}(\boldsymbol{x}) = \boldsymbol{x}$. *Define* $\delta_\theta(\boldsymbol{x}_{t_j}) := \boldsymbol{f}_\theta^{(t_j)}(\boldsymbol{x}_{t_j}) - \boldsymbol{f}_\theta^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}})$. *Then,*

$$\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0 = \sum_{j=1}^{m} \delta_\theta(\boldsymbol{x}_{t_j}), \quad \|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2 \le \sqrt{m}\left(\sum_{j=1}^{m} \|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2\right)^{1/2}. \tag{64}$$

Proof. Fix a partition $0 = t_0 < t_1 < \cdots < t_m = t$ and assume $\boldsymbol{f}_\theta^{(0)}(\boldsymbol{x}) = \boldsymbol{x}$. By adding and subtracting intermediate terms, we obtain the telescoping identity

$$\begin{aligned}\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t) - \boldsymbol{x}_0 &= \big(\boldsymbol{f}_\theta^{(t_m)}(\boldsymbol{x}_{t_m}) - \boldsymbol{f}_\theta^{(t_{m-1})}(\boldsymbol{x}_{t_{m-1}})\big) \;+\; \cdots \;+\; \big(\boldsymbol{f}_\theta^{(t_1)}(\boldsymbol{x}_{t_1}) - \boldsymbol{f}_\theta^{(t_0)}(\boldsymbol{x}_{t_0})\big) \\ &= \sum_{j=1}^{m} \delta_\theta(\boldsymbol{x}_{t_j}),\end{aligned}$$

where $\delta_\theta(\boldsymbol{x}_{t_j}) := \boldsymbol{f}_\theta^{(t_j)}(\boldsymbol{x}_{t_j}) - \boldsymbol{f}_\theta^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}})$ and for the final time-step we set $\boldsymbol{f}_\theta^{(0)}(\boldsymbol{x}_{t_0}) = \boldsymbol{f}_\theta^{(0)}(\boldsymbol{x}_0) = \boldsymbol{x}_0$.

Furthermore, for the bound, we stack the increments as columns of a matrix $U := [\,\delta_\theta(\boldsymbol{x}_{t_1})\;\; \delta_\theta(\boldsymbol{x}_{t_2})\;\; \cdots\;\; \delta_\theta(\boldsymbol{x}_{t_m})\,] \in \mathbb{R}^{d\times m}$ and let $\mathbf{1} \in \mathbb{R}^m$ denote the all-ones vector. Then

$$\sum_{j=1}^{m} \delta_\theta(\boldsymbol{x}_{t_j}) \;=\; U\,\mathbf{1}.$$

By the Cauchy–Schwarz inequality in Frobenius/Euclidean norms,

$$\big\|U\,\mathbf{1}\big\|_2 \;\le\; \|U\|_F\,\|\mathbf{1}\|_2 \;=\; \Big(\sum_{j=1}^{m} \|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2\Big)^{1/2}\sqrt{m}.$$

Combining with the telescoping identity yields

$$\boxed{\left\|\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)-\boldsymbol{x}_0\right\|_2 \;=\; \left\|\sum_{j=1}^{m}\delta_\theta(\boldsymbol{x}_{t_j})\right\|_2 \;\le\; \sqrt{m}\left(\sum_{j=1}^{m}\|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2\right)^{1/2}.} \tag{65}$$

Remark. An alternative derivation of the same bound follows from the triangle inequality and Cauchy–Schwarz in $\mathbb{R}^m$:

$$\left\|\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)-\boldsymbol{x}_0\right\|_2 \le \sum_{j=1}^{m}\|\delta_\theta(\boldsymbol{x}_{t_j})\|_2 \le \sqrt{m}\left(\sum_{j=1}^{m}\|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2\right)^{1/2}. \qquad \square$$

Proposition 2. *Assume the Gaussian clean-sample model $p_\psi^{(t)}(\boldsymbol{x}_0|\boldsymbol{x}_t)=\mathcal{N}(\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t),\sigma_t^2\boldsymbol{I})$, for each $\psi\in\{\theta,\phi\}$ (**Assumption 1**, Appendix B), with $\boldsymbol{x}_t=\sqrt{\alpha_t}\boldsymbol{x}_0+\sqrt{1-\alpha_t}\epsilon$ and $\epsilon\sim\mathcal{N}(\boldsymbol{0},\boldsymbol{I})$, and the assumptions of **Proposition 1** for both θ and ϕ. Let $\delta_\psi(\boldsymbol{x}_{t_j}):=\boldsymbol{f}_\psi^{(t_j)}(\boldsymbol{x}_{t_j})-\boldsymbol{f}_\psi^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}})$. Then the implicit reward $l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)$ decomposes exactly as:*

$$l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)=-\tfrac{1}{2\sigma_t^2}\Big[\underbrace{\textstyle\sum_{j=1}^{m}\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j})}_{\textit{timestep-local}}+\underbrace{2\textstyle\sum_{j<k}\left(\langle\delta_\theta(\boldsymbol{x}_{t_j}),\delta_\theta(\boldsymbol{x}_{t_k})\rangle-\langle\delta_\phi(\boldsymbol{x}_{t_j}),\delta_\phi(\boldsymbol{x}_{t_k})\rangle\right)}_{\textit{cross-timestep interactions}}\Big], \tag{66}$$

where $\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j})=\|\delta_\theta(\boldsymbol{x}_{t_j})\|_2^2-\|\delta_\phi(\boldsymbol{x}_{t_j})\|_2^2$.

Proof. Throughout, write $\delta_{\theta,j}:=\delta_\theta(\boldsymbol{x}_{t_j})$ and $\delta_{\phi,j}:=\delta_\phi(\boldsymbol{x}_{t_j})$ for $j\in\{1,\dots,m\}$, and let d denote the dimension of $\boldsymbol{x}_0$. The proof proceeds in four steps, each of which is an equality.

Step 1 (Gaussian log-likelihood ratio). Under Assumption 1, both clean-sample conditionals are isotropic Gaussians with the same variance σ_t^2 and means $\mu_\theta:=\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)$ and $\mu_\phi:=\boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t)$. For $\psi\in\{\theta,\phi\}$,

$$\log p_\psi(\boldsymbol{x}_0|\boldsymbol{x}_t)=-\frac{d}{2}\log(2\pi\sigma_t^2)-\frac{1}{2\sigma_t^2}\|\boldsymbol{x}_0-\mu_\psi\|_2^2.$$

The normalization term does not depend on ψ and therefore cancels in the log-ratio, giving

$$l_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)=\log\left(\frac{p_\theta(\boldsymbol{x}_0|\boldsymbol{x}_t)}{p_\phi(\boldsymbol{x}_0|\boldsymbol{x}_t)}\right)=-\frac{1}{2\sigma_t^2}\Big(\|\boldsymbol{x}_0-\boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2-\|\boldsymbol{x}_0-\boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2\Big). \tag{67}$$

Step 2 (Telescoping the residuals). By the assumptions of Proposition 1, $t_0=0$, $t_m=t$, $\boldsymbol{x}_{t_0}=\boldsymbol{x}_0$, and $\boldsymbol{f}_\psi^{(0)}(\boldsymbol{x})=\boldsymbol{x}$. Hence, $\boldsymbol{f}_\psi^{(t_0)}(\boldsymbol{x}_{t_0})=\boldsymbol{x}_0$ for $\psi\in\{\theta,\phi\}$. With $\alpha_0=1$, the coupled construction of Appendix E.2 also gives $\boldsymbol{x}_{t_0}=\boldsymbol{x}_0$. Telescoping across the intermediate predictions therefore gives

$$\begin{aligned}\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t)-\boldsymbol{x}_0&=\boldsymbol{f}_\psi^{(t_m)}(\boldsymbol{x}_{t_m})-\boldsymbol{f}_\psi^{(t_0)}(\boldsymbol{x}_{t_0})\\&=\sum_{j=1}^{m}\left(\boldsymbol{f}_\psi^{(t_j)}(\boldsymbol{x}_{t_j})-\boldsymbol{f}_\psi^{(t_{j-1})}(\boldsymbol{x}_{t_{j-1}})\right)\\&=\sum_{j=1}^{m}\delta_{\psi,j}.\end{aligned} \tag{68}$$

Since $\|\boldsymbol{x}_0-\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t)\|_2=\|\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t)-\boldsymbol{x}_0\|_2$, it follows that

$$\|\boldsymbol{x}_0-\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t)\|_2^2=\left\|\sum_{j=1}^{m}\delta_{\psi,j}\right\|_2^2.$$

Note that Eq. (68) is purely algebraic and does not require any additional modeling assumption beyond the endpoint conditions above. In particular, the same coupled points $\boldsymbol{x}_{t_j}$ are used for both θ and ϕ.

Step 3 (Expanding the squared norm of a sum). For any vectors $\boldsymbol{a}_1, \dots, \boldsymbol{a}_m \in \mathbb{R}^d$, bilinearity and symmetry of the inner product give

$$\begin{aligned}\left\|\sum_{j=1}^{m} \boldsymbol{a}_j\right\|_2^2 &= \left\langle \sum_{j=1}^{m} \boldsymbol{a}_j, \sum_{k=1}^{m} \boldsymbol{a}_k \right\rangle \\ &= \sum_{j=1}^{m}\sum_{k=1}^{m} \langle \boldsymbol{a}_j, \boldsymbol{a}_k \rangle \\ &= \sum_{j=1}^{m} \|\boldsymbol{a}_j\|_2^2 + 2\sum_{j<k} \langle \boldsymbol{a}_j, \boldsymbol{a}_k \rangle,\end{aligned} \tag{69}$$

where the last equality separates the diagonal terms $j = k$ and pairs each off-diagonal term (j, k) with (k, j). Applying this identity with $\boldsymbol{a}_j = \delta_{\psi,j}$ yields, for $\psi \in \{\theta, \phi\}$,

$$\|\boldsymbol{x}_0 - \boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t)\|_2^2 = \sum_{j=1}^{m} \|\delta_{\psi,j}\|_2^2 + 2\sum_{j<k} \langle \delta_{\psi,j}, \delta_{\psi,k} \rangle. \tag{70}$$

Step 4 (Substituting and grouping). Subtracting (70) for $\psi = \phi$ from (70) for $\psi = \theta$ and grouping terms by type gives

$$\|\boldsymbol{x}_0 - \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t)\|_2^2 - \|\boldsymbol{x}_0 - \boldsymbol{f}_\phi^{(t)}(\boldsymbol{x}_t)\|_2^2 = \sum_{j=1}^{m} \underbrace{\left(\|\delta_{\theta,j}\|_2^2 - \|\delta_{\phi,j}\|_2^2\right)}_{=\Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j})} + 2\sum_{j<k} \Big(\langle \delta_{\theta,j}, \delta_{\theta,k} \rangle - \langle \delta_{\phi,j}, \delta_{\phi,k} \rangle \Big). \tag{71}$$

Substituting this expression into Eq. (67) gives Eq. (66). Since every step above is an equality, the decomposition is exact under Assumption 1 and the assumptions of Proposition 1. □

From the exact decomposition to the `CePU` surrogate. Let $c_t := 1/(2\sigma_t^2) > 0$, and define

$$L := \sum_{j=1}^{m} \Delta_\theta^{\mathrm{C}}(\boldsymbol{x}_{t_j}), \qquad X := \sum_{j<k} \Big(\langle \delta_{\theta,j}, \delta_{\theta,k} \rangle - \langle \delta_{\phi,j}, \delta_{\phi,k} \rangle \Big) \tag{72}$$

as the timestep-local and cross-timestep contributions, respectively. Proposition 2 then gives $l_\theta = -c_t(L + 2X)$, whereas the `CePU` reward in (8) retains only the timestep-local contribution, $\tilde{l}_\theta = -c_t L$. The cross-timestep term couples consistency increments evaluated at different timesteps. Consequently, unlike the timestep-local term, it is not directly available from a single sampled adjacent transition. Retaining only the local contribution therefore yields a reward that can be evaluated using the same stochastic, per-timestep sampling procedure employed during DPO training. Three consequences follow:

- *Exactness for a one-step decomposition.* If the entire interval from $t_0 = 0$ to $t_m = t$ consists of a single increment ($m = 1$), the sum over $j < k$ is empty. Hence $X = 0$ and $\tilde{l}_\theta = l_\theta$.
- *Sign agreement under bounded cross-timestep interactions.* A sufficient condition for $\tilde{l}_\theta$ and l_θ to have the same sign is $2|X| < |L|$. Indeed, since $c_t > 0$,

  $$\operatorname{sign}(l_\theta) = -\operatorname{sign}(L + 2X), \qquad \operatorname{sign}(\tilde{l}_\theta) = -\operatorname{sign}(L),$$

  and the condition implies $L \neq 0$. If $L > 0$, then $L + 2X \geq L - 2|X| > 0$; if $L < 0$, then $L + 2X \leq L + 2|X| < 0$.

  The same argument applies to the DPO margin. Because the preferred and dispreferred samples share the same timestep t, and hence the same c_t (Algorithm 1),

  $$l_\theta(\boldsymbol{x}_0^+|\boldsymbol{x}_t^+) - l_\theta(\boldsymbol{x}_0^-|\boldsymbol{x}_t^-) = -c_t\Big[(L^+ - L^-) + 2(X^+ - X^-)\Big],$$

  whereas the corresponding surrogate margin is

  $$-c_t(L^+ - L^-).$$

  Thus, a sufficient condition for the two margins to have the same sign is

  $$2|X^+ - X^-| < |L^+ - L^-|.$$

- *No unconditional guarantee.* Without additional assumptions on X, the signs of the exact and surrogate rewards need not agree. For example, take $m = 2$, scalar increments, $\sigma_t^2 = 1$, $\delta_\theta = (1, -1)$, and $\delta_\phi = (0, 1)$. Then

$$L = (1^2 + (-1)^2) - (0^2 + 1^2) = 1, \qquad X = (1)(-1) - (0)(1) = -1.$$

Hence, the exact reward is

$$l_\theta = -\tfrac{1}{2}(L + 2X) = +\tfrac{1}{2},$$

whereas the surrogate is

$$\tilde{l}_\theta = -\tfrac{1}{2}L = -\tfrac{1}{2}.$$

Here $2|X| = 2 > |L| = 1$, so the sufficient sign-agreement condition is violated.

We therefore interpret $\tilde{l}_\theta$ as a timestep-local surrogate obtained by retaining the local component of the exact likelihood-ratio decomposition while discarding cross-timestep interactions. In general, this truncation does not guarantee equality with, or even sign agreement with, the exact likelihood ratio; the sufficient conditions above characterize cases in which sign agreement is preserved. Accordingly, `CePU` does not rely on Proposition 2 for a convergence or optimality guarantee. Rather, the proposition provides a likelihood-based motivation for the local consistency reward used by `CePU`, whose effectiveness is evaluated empirically in Section 3 and Appendix F.

D Directly Unlearning on FSD Model

Table A: Direct unlearning on the few-step distilled (FSD) model (SD1.5-Distilled → Unlearning) vs. a two-stage pipeline that first unlearns the base diffusion model and then distills it (SD1.5 → Unlearning → Distillation).

Metrics		SD1.5	SD1.5 → Unlearning	SD1.5 → Unlearning→ Distillation (**15 mins + 24 hours**)	SD1.5-Distilled	SD1.5-Distilled → Unlearning (**15 mins**)
I2P NudeNet Detections (↓)	Buttocks	18	0	1	15	0
	Female Breast	252	19	17	253	17
	Female Genitalia	10	1	1	12	1
	Male Genitalia	11	1	1	10	1
	Anus	0	0	0	0	0
	Total	291	21	20	290	19
CS (↑)		0.31660	0.31271	0.30258	0.30235	0.30232

A natural approach to bring in safety interventions to FSD models is to first perform unlearning on the base diffusion model (BM) and then distill the edited BM into an FSD model. However, this two-stage pipeline incurs substantial computational overhead due to the expensive distillation process. In contrast, we directly apply `CePU` to the FSD model. As shown in Table A, direct unlearning on FSD model using `CePU` achieves performance comparable to the two-stage pipeline in terms of both unlearning effectiveness and utility preservation. Crucially, it avoids the costly distillation step. In our case we distill an SD1.5 model, using LCM distillation, for $\sim$ 24 hours on 4×A5000 GPUs (24GB each), noting that distillation can be run longer to further improve generation quality. In contrast, `CePU` performs unlearning in $\sim$ 15 minutes on a single A5000 GPU. This results in orders-of-magnitude lower time and computational overhead compared to unlearning followed by distillation while directly editing the deployed FSD model, making the approach both efficient and aligned with deployment-time objectives. Unlearning SD1.5 before distillation is conducted using DUO [66].

E Training and Evaluation Details

For all preference-driven unlearning baselines, including DPO [89], DUO [66], PSO [63], SafetyDPO [54], and `CePU`, we fine-tune using LoRA [45] with rank 32 and the AdamW optimizer. Following prior work, we do not apply LoRA to the cross-attention layers to avoid overfitting to specific text prompts [66, 31]. At initialization, β scales the preference-loss gradient. Following the rescaling strategy in [66], we also vary the learning rate according to $\eta(\beta) = 10^{-4}(100/\beta)$. The reported sweeps therefore characterize a joint (β, η) schedule rather than changing β alone. Using $\beta = 100$ as our default setting, we adopt a learning rate of 1×10^{-4} and a batch size of 4. We use a learning rate of 10^{-4} at $\beta = 100$ as the reference configuration and scale the learning rate with β consistently across methods, therefore, we use this configuration as our base setup and then modulate β and the learning rate w.r.t. β, as discussed, consistently for all methods. Moreover, our proposed `CePU`

objective uses the consistency error as a proxy reward. To compute the consistency error, we sample a time t_j and set t_{j-1} to a fixed offset k such that $t_{j-1} = t_j - k$, for ease of implementation and efficiency. For our experiments, we set $k = 20$ following [59]. Using this setup, we train all methods for 500 iterations for both the nudity and identity unlearning tasks. The preference-driven baselines require no more than 15 minutes to fine-tune the FSD models for 500 iterations on a workstation with an AMD EPYC 7413 24-core CPU, 512 GB RAM, and 4 NVIDIA A5000 GPUs.

For evaluating all unlearning methods by generating images from the models after conducting the unlearning. Primarily we sample image for 4 steps with LCM scheduler [59] with classifier-free guidance scale of 0 (disabled).

E.1 Training Dataset Creation

Following [66], we construct paired samples $(\boldsymbol{x}_0^+, \boldsymbol{x}_0^-)$ with SDEdit [62] to obtain $\boldsymbol{x}_0^+$ from $\boldsymbol{x}_0^-$ by removing undesirable concepts while preserving non-target semantics. For each unsafe concept $\boldsymbol{c}^-$, we first generate an undesirable image $\boldsymbol{x}_0^-$; then produce a desirable counterpart $\boldsymbol{x}_0^+$ by applying SDEdit to $\boldsymbol{x}_0^-$ at a mid-range edit strength $\tau \in (0, 1)$ using the preferred prompt $\boldsymbol{c}^+$. Specifically, we use $\tau = 0.6$, *i.e.*, 60% strength, given there are original 1000 diffusion steps. This procedure preserves global scene semantics while modifying only concept-specific attributes. We use these pairs as selective counterfactual supervision for preference optimization across all preference-driven unlearning baselines [89, 66, 54, 63], including `CePU` for our analysis. In Table B and C we provide the training examples that we generate using ChatGPT [11] used to generate these pairs for the celebrity unlearning task, inspired by [50]. For nudity unlearning we use the prompts directly sampled by [50] as shown in Table D. For object-level unlearning we do not use the SDEdit procedure, rather we sample images using the prompt `a picture of <class-name>`.

Hyperparameter selection and reporting. We selected the retention weight λ using Angelina Jolie identity unlearning and I2P nudity unlearning as validation tasks. For each task, we selected the operating point on the unlearning–utility Pareto curve closest to the ideal of 100% unlearning accuracy (identity) or DSR (nudity) and zero LPIPS (Figure 6). This yielded $\lambda = 100$ for identity unlearning and $\lambda = 10$ for nudity unlearning; these task-specific values were then fixed across the remaining identities, model backbones, and red-teaming benchmarks. The additional identities and adversarial prompt sets were not used to select λ. For β, we report sweeps to characterize the unlearning–utility trade-off of each preference-based method, rather than selecting a single universally optimal value (Tables H, I, J, L, and K). For the main-paper comparisons, we chose representative operating points from these sweeps to compare retention at similar or stronger levels of unlearning. Specifically, for identity unlearning, we report $\beta = 250$ for DPO, DUO, PSO, and SafetyDPO and $\beta = 100$ for `CePU`; for nudity unlearning, we report $\beta = 100$ for these baselines and $\beta = 500$ for `CePU`. These β settings therefore represent operating points chosen from the reported sweeps, rather than values selected on a separate held-out validation set.

E.2 Computing the Consistency Error

For each training example, we draw a single Gaussian noise sample ϵ and reuse it at both noise levels, so that $\boldsymbol{x}_{t_j}$ and $\boldsymbol{x}_{t_{j-1}}$ are coupled points on the same forward-noising path:

$$\boldsymbol{x}_{t_j} = \sqrt{\alpha_{t_j}}\,\boldsymbol{x}_0 + \sqrt{1-\alpha_{t_j}}\,\epsilon, \qquad \boldsymbol{x}_{t_{j-1}} = \sqrt{\alpha_{t_{j-1}}}\,\boldsymbol{x}_0 + \sqrt{1-\alpha_{t_{j-1}}}\,\epsilon, \qquad t_{j-1} = t_j - k. \tag{73}$$

For the trainable model, gradients flow only through the prediction at the noisier timestep t_j; the lower-noise prediction is a stop-gradient target, denoted $\mathrm{sg}[\cdot]$. The reference model ϕ is frozen throughout. The same construction is used for $\mathcal{L}_{\texttt{C-DPO}}$ (11) and $\mathcal{L}_{\texttt{RET}}$ (13). Algorithm 1 summarizes one optimization step; in practice, all losses are averaged over the mini-batch.

Algorithm 1 One CePU optimization step. The same coupled construction is used in $\mathcal{L}_{\texttt{C-DPO}}$ and $\mathcal{L}_{\texttt{RET}}$.

Require: Preference pair $(\boldsymbol{x}_0^+, \boldsymbol{x}_0^-)$ with prompts $(\boldsymbol{c}^+, \boldsymbol{c}^-)$; trainable $\boldsymbol{f}_\theta$; frozen reference $\boldsymbol{f}_\phi$; schedule $\{\alpha_t\}_{t=0}^T$ with $\alpha_0 = 1$; boundary condition $\boldsymbol{f}_\psi^{(0)}(\boldsymbol{x}) = \boldsymbol{x}$ for $\psi \in \{\theta, \phi\}$; offset k; β; λ

$\mathcal{L}_{\texttt{RET}} \leftarrow \left\| \boldsymbol{f}_\theta^{(t)}(\boldsymbol{x}_t^+, \boldsymbol{c}^+) - \mathrm{sg}\left[\boldsymbol{f}_\phi^{(s)}(\boldsymbol{x}_s^+, \boldsymbol{c}^+)\right] \right\|_2^2$ ▷ Eq. (13)

Update θ with $\nabla_\theta\left(\mathcal{L}_{\texttt{C-DPO}} + \lambda\,\mathcal{L}_{\texttt{RET}}\right)$; keep ϕ frozen ▷ Eq. (14)

E.3 Identity Unlearning

For identity unlearning, we generate 64 images per target identity using 64 prompts, examples of which are shown in Tables B and C. Using SDEdit, we construct counterfactual training pairs by editing each generated image with a corresponding identity-agnostic prompt, where the identity keyword is replaced with a neutral term (*e.g.*, *a man* or *a woman*). This training data creation protocol is followed by all preference-based methods [89, 66, 63, 54] including CePU. All preference-based methods use the same sampled dataset to ensure a controlled comparison of unlearning performance.

For evaluation, we use a disjoint set of 64 test prompt templates containing the target identity to generate images and measure target-identity accuracy ($\mathcal{A}_{\text{target}}$) using the GCD (Giphy-Celeb-Detector) classifier [6]. To assess utility preservation, we also generate 64 images using the identity-agnostic versions of the test prompts and compute LPIPS with respect to the FSD baseline.

Finally, to evaluate unintended degradation on other identities, we generate 64 images for each of four non-target celebrities (Gal Gadot, Scarlett Johansson, Bradley Cooper, and Jake Gyllenhaal) and report the average recognition accuracy ($\mathcal{A}_{\text{others}}$) using the GCD classifier. Note that during unlearning we do not explicitly enforce retention of other identities; the retention loss is computed only using identity-agnostic prompts and images.

All methods considered in our study, including preference-based [89, 66, 63, 54], zero-shot [99, 32], and fine-tuning approaches[31, 51, 87], are evaluated using the same protocol described above.

E.4 Nudity Unlearning

For nudity unlearning, following Ko *et al.* [50], we construct 800 paired prompts $(\boldsymbol{c}^+, \boldsymbol{c}^-)$ where $\boldsymbol{c}^-$ contains nudity-enforcing keywords and $\boldsymbol{c}^+$ is obtained by removing the nudity-specific terms while preserving the remaining prompt structure. Unsafe training samples are first generated using the 800 nudity-enforcing prompts introduced by Ko *et al.* [50] (examples shown in Table D), after which a counterfactual preference pair is constructed for each sample using the corresponding sanitized prompt. Paired preference images $(\boldsymbol{x}_0^+, \boldsymbol{x}_0^-)$ are generated using SDEdit [62] as described in Section 2.5, enabling controlled semantic edits while preserving the underlying scene composition and visual structure. Representative examples are shown in Figure B. This paired-data construction protocol is consistently adopted across all preference-based baselines [89, 66, 63, 54], including `CePU`, and the same sampled dataset is used across all preference-based methods to ensure a fair, head-to-head comparison.

For evaluation, we assess unlearning effectiveness using NudeNet detections [9] by counting exposed-body-part predictions, including Female Genitalia, Male Genitalia, Female Breast, Buttocks, and Anus, on red-teaming benchmarks from prior work: Inappropriate Image Prompts (I2P) [78], Ring-A-Bell (RAB) [88], SneakyPrompt (SP) [96], Prompting4Debugging (P4D) [23], and Multi-Modal Attack (MMA) [95], including both adversarial (MMA-A) and sanitized (MMA-S) variants. None of these evaluation prompts are used during training. We report Defense Success Rate (DSR), defined as the percentage reduction in NudeNet detections relative to the original FSD model. To evaluate utility preservation after unlearning, we additionally compute CLIP score (CS) [43] and LPIPS [103] on 1000 benign LAION prompts [79] sampled following [95].

All methods considered in our study, including preference-based [89, 66, 63, 54], zero-shot [99, 32], and fine-tuning approaches [31, 51, 87], are evaluated using the same protocol described above.

E.5 Object-level Unlearning

For object-level unlearning, we generate 90 images per class (using different random seeds) with the prompt template `a picture of <class-name>`, where `<class-name>` corresponds to classes from Imagenette or the fine-grained object categories introduced in [87]. During training, one class is designated as the target concept to be unlearned, while all remaining classes are treated as concepts to be retained. This training data creation protocol is followed by all preference-based methods [89, 66, 63, 54] including `CePU`, rather the same sampled dataset is used to ensure a fair, head-to-head comparison of the unlearning performance.

For evaluation, we generate 500 images per class (with different seeds) using a distinct prompt template `Image of <class-name>`. We report the target-class accuracy ($\mathcal{A}_{\text{target}}$), the average accuracy on non-target classes ($\mathcal{A}_{\text{others}}$), and the harmonic mean ($\mathcal{H}_{\text{mean}}$) between $1 - \mathcal{A}_{\text{target}}$ and $\mathcal{A}_{\text{others}}$. To assess utility preservation, we also compute LPIPS on samples generated from non-target classes relative to the FSD baseline. This setup is applied to both Imagenette class unlearning (Tables 3 and E and F) and fine-grained object unlearning (Table G).

All methods considered in our study, including preference-based [89, 66, 63, 54], zero-shot [99, 32], and fine-tuning approaches[31, 51, 87], are evaluated using the same protocol described above.

F Additional Results

F.1 Additional Object-Level Unlearning on Imagenette

We additionally benchmark object-level unlearning on the 10 Imagenette classes against both zero-shot-based and preference-driven baselines in Tables E and F. `CePU` achieves complete removal for all target classes, driving the average target accuracy $\mathcal{A}_{\text{target}}$ to 0.00, while maintaining strong retention on non-target classes ($\mathcal{A}_{\text{others}} = 60.85$) with low perceptual drift from the original FSD model (LPIPS $= 0.0900$). Note that, $\mathcal{A}_{\text{others}}$ for these experiments are the average across classes not being unlearned. Compared to zero-shot alternatives, UCE [32] provides reasonably strong unlearning but at substantially higher perceptual distortion (LPIPS $= 0.2894$), while SAFREE

[99] degrades both removal and retention performance. Compared to preference-based methods for which we adopt a similar strategy as discussed in Section 3.3 to avoid ambiguity of preferred counterpart examples, DUO [66] preserves image statistics well (LPIPS $= 0.0630$) but fails to fully erase target concepts ($\mathcal{A}_{\text{target}} = 14.52$); PSO [63] and SafetyDPO [54] show larger trade-offs between removal and retention, and DPO [89] exhibits the weakest overall balance. Overall, CePU obtains the highest harmonic mean ($\mathcal{H}_{\text{mean}} = 75.66$) across all methods, demonstrating that it delivers the most favorable trade-off between precise object removal and preservation of non-target classes. In Table F, the preference-driven baselines (DPO, DUO, PSO, and SafetyDPO) are reported with $\beta = 100$, corresponding to their best $\mathcal{A}_{\text{target}}$ reduction. For CePU, we report results with $\beta = 500$ and $\lambda = 10$ in Tables 3, E, and F.

FADE [87]	2.00	1.1881	22.40	0.0857	99.80	0.0481	58.20	0.1420	96.00	0.0640	100.00	0.0551	**75.28**	**0.0790**
CePU **(Ours)**	0.00	1.1953	35.00	0.0518	100.00	0.0387	57.80	0.0824	96.00	0.0583	100.00	0.0528	**77.76**	**0.0568**

Unlearning a target concept should ideally avoid degrading semantically related concepts. To evaluate this property, we analyze the retention of dog breeds that are semantically adjacent to the targeted concept *German Shepherd*, that include *Malinois*, *Rottweiler*, *Norwegian Elkhound*, *Labrador Retriever*, *and Golden Retriever* as identified by [87]. Table G reports the classification accuracy and LPIPS distance relative to the FSD model for target and these adjacent concepts after unlearning. The target concept accuracy $\mathcal{A}_{\text{target}}$ measures the effectiveness of unlearning (lower is better), while $\mathcal{A}_{\text{others}}$ and LPIPS quantify the retention of adjacent concepts, where higher $\mathcal{A}_{\text{others}}$ and lower LPIPS indicate better preservation. Our method achieves complete removal of the target concept ($\mathcal{A}_{\text{target}} = 0$) while preserving adjacent concepts more effectively than FADE [87], achieving higher average accuracy (77.76 % vs. 75.28 %) and lower perceptual deviation from the base model (LPIPS 0.0568 vs. 0.0790). These results suggest that CePU performs more targeted concept removal, mitigating unintended collateral degradation of semantically related concepts. The CePU numbers are provided for $\beta = 500$ and $\lambda = 10$.

F.3 Extended Identity Unlearning Results

Tables H and I extend the identity-unlearning comparison by reporting results for preference-based methods across multiple β values on DS-V8-LCM [5] and DS-V7-LCM [3]. Consistent with the role of β, we observe a clear unlearning–utility trade-off: lower β enforces stronger forgetting but often degrades preservation of other identities, while higher β improves retention at the expense of weaker target suppression. Across both targets and both FSD backbones, CePU traces a stronger Pareto frontier than prior preference-based approaches, achieving superior balance between $\mathcal{A}_{\text{target}}$ and $\mathcal{A}_{\text{others}}$. In particular, on DS-V8-LCM, CePU attains complete removal for all reported β values while substantially improving non-target retention as β increases, leading to the best harmonic

mean at β=1000. On DS-V7-LCM, where the task is comparatively harder, CePU remains robust and competitive across β, again offering strong controllability over the trade-off. These results reinforce that CePU is not tied to a narrow hyperparameter regime and consistently yields favorable identity-unlearning performance across settings.

Table H: Comparison of unlearning methods for identity removal on DS-V8-LCM. Extended results corresponding to Table 1. For preference-based methods, *italicized* method name rows denote the configurations reported in the main manuscript.

F.4 Extended Nudity Unlearning Results

We further report nudity-unlearning results across multiple β values for preference-based methods on DS-V8-LCM [5], DS-V7-LCM [3], and SD-Turbo [10] in Tables J, L, and K. Across all three backbones, β induces a clear safety–utility trade-off: low β strongly suppresses unsafe generations, whereas high β better preserves the original model distribution but weakens unlearning. Despite this trade-off, CePU consistently lies on a more favorable frontier than prior preference-based baselines. On DS-V8-LCM and DS-V7-LCM, CePU with β=100 achieves the strongest suppression, reducing total NudeNet detections from 3120 to 61 and from 2554 to 68, corresponding to 98.04% and 97.34% DSR, respectively. On SD-Turbo, CePU is even stronger: β=250 achieves the best overall suppression with only 5 total detections and 99.43% DSR, while β=500 provides a particularly attractive trade-off, retaining near-identical suppression (6 detections, 99.32% DSR) with substantially improved LPIPS and CS alignment. By contrast, alternative preference-based methods deteriorate sharply as β increases, often approaching the unsafe baseline while only improving perceptual similarity. These results reinforce that CePU is robust across backbones and hyperparameter settings, and provides effective control over the safety–utility trade-off in nudity unlearning.

Table J: Extended comparison of nudity-unlearning methods across multiple β values on red-teaming prompt sets. We report NudeNet detections, average DSR, LPIPS, and CS to assess the safety–utility trade-off. Extended results from Table 2. For preference-based methods, *italicized* method name rows denote the configurations reported in the main manuscript.

F.5 Robustness to Multilingual Prompt Attacks

We evaluate robustness to multilingual prompt attacks by translating unsafe MMA prompts [95] into German, Italian, and French using ChatGPT. We compare CePU with DPO, DUO, PSO, and SafetyDPO on DS-V8-LCM [5] and SD-Turbo [10] across $\beta \in \{100, 250, 500\}$. Tables M and N report nudity detections for each language, their total, and the aggregate defense success rate (DSR). Specifically, DSR is the percentage reduction in total detections relative to the corresponding original FSD model, whose total is 1205 for DS-V8-LCM and 347 for SD-Turbo. The tables additionally report LPIPS, DINO-I, DreamSim, CLIP-I, and CLIP-T to characterize retention and prompt–image alignment.

On DS-V8-LCM, CePU produces four total detections at each evaluated β, corresponding to 99.67% aggregate DSR. On SD-Turbo, it produces one, one, and two detections at $\beta = 100$, 250, and 500, respectively, corresponding to 99.71%, 99.71%, and 99.42% DSR. In contrast, the aggregate DSR of the competing preference-based methods decreases substantially as β increases. At $\beta = 500$, their DSR ranges from 13.61% to 28.71% on DS-V8-LCM and from 20.17% to 27.09% on SD-Turbo.

The results also illustrate an unlearning–retention trade-off. At $\beta = 100$, the competing methods on DS-V8-LCM already achieve 99.34%–99.59% DSR with lower LPIPS than CePU. Within CePU, increasing β from 100 to 500 reduces LPIPS from 0.135 to 0.083 on DS-V8-LCM while maintaining 99.67% DSR. On SD-Turbo, LPIPS decreases from 0.198 to 0.079, while DSR changes from 99.71% to 99.42%. These findings support strong suppression under the evaluated German, Italian, and French prompt attacks across the tested preference strengths, while retaining the need to assess utility alongside unlearning effectiveness.

F.6 Extension to Flow-Matching Models

We extend CePU to velocity-parameterized flow-matching models [27] by expressing their predictions in clean-sample space. We then evaluate this extension on SD3-Turbo [57], an MMDiT-based [27] few-step distilled flow-matching model, for nudity unlearning.

Clean-sample prediction from velocity. Consider an interpolation path

$$\boldsymbol{x}_t = a(t)\boldsymbol{x}_0 + b(t)\epsilon, \qquad \epsilon \sim \mathcal{N}(\mathbf{0}, \mathbf{I}), \tag{74}$$

where $a(t)$ and $b(t)$ are differentiable scalar functions. The corresponding conditional target velocity is

$$u_t(\boldsymbol{x}_t \mid \boldsymbol{x}_0, \epsilon) = \dot{a}(t)\boldsymbol{x}_0 + \dot{b}(t)\epsilon. \tag{75}$$

A velocity model $v_\psi(\boldsymbol{x}_t, t, \boldsymbol{c})$ is trained to regress these targets. Solving the linear system after substituting the predicted velocity gives the clean-sample prediction

$$\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t, \boldsymbol{c}) = \frac{\dot{b}(t)\boldsymbol{x}_t - b(t)v_\psi(\boldsymbol{x}_t, t, \boldsymbol{c})}{a(t)\dot{b}(t) - b(t)\dot{a}(t)}, \tag{76}$$

provided that $a(t)\dot{b}(t) - b(t)\dot{a}(t) \neq 0$. Here, $\psi \in \{\theta, \phi\}$ denotes either the trainable model or the frozen reference model.

For the rectified-flow path $\boldsymbol{x}_t = (1-t)\boldsymbol{x}_0 + t\epsilon$, with $t \in [0, 1]$, we have $a(t) = 1 - t$ and $b(t) = t$. Consequently,

$$\boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t, \boldsymbol{c}) = \boldsymbol{x}_t - t\, v_\psi(\boldsymbol{x}_t, t, \boldsymbol{c}). \tag{77}$$

This expression uses a time convention in which $t = 0$ corresponds to clean data and $t = 1$ to noise.

Consistency-based preference objective. For two times $s < t$, we construct coupled states $\boldsymbol{x}_t$ and $\boldsymbol{x}_s$ using the same clean sample $\boldsymbol{x}_0$ and noise realization ϵ in Eq. (74). The squared clean-prediction consistency error is

$$E_\psi^{\mathrm{FM}}(\boldsymbol{x}_t, \boldsymbol{x}_s, \boldsymbol{c}) = \left\| \boldsymbol{f}_\psi^{(t)}(\boldsymbol{x}_t, \boldsymbol{c}) - \boldsymbol{f}_\psi^{(s)}(\boldsymbol{x}_s, \boldsymbol{c}) \right\|_2^2. \tag{78}$$

The corresponding reference-relative signal is

$$\Delta_\theta^{\mathrm{C,FM}}(\boldsymbol{x}_t, \boldsymbol{x}_s, \boldsymbol{c}) = E_\theta^{\mathrm{FM}}(\boldsymbol{x}_t, \boldsymbol{x}_s, \boldsymbol{c}) - E_\phi^{\mathrm{FM}}(\boldsymbol{x}_t, \boldsymbol{x}_s, \boldsymbol{c}). \tag{79}$$

Substituting these clean-sample predictions and consistency signals into the preference and retention losses preserves the objective structure of CePU (Eq. (14)). Thus, the objective can accommodate the flow-matching parameterization without requiring noise-prediction outputs.

Evaluation on SD3-Turbo. Table O compares CePU with DPO and DUO across $\beta \in \{100, 250, 500, 1000\}$. We report nudity detections on I2P, P4D, MMA-A, MMA-S, and RAB. Total denotes their sum, and DSR is computed as

$$\mathrm{DSR} = 100\left(1 - \frac{N_{\mathrm{method}}}{N_{\mathrm{base}}}\right), \qquad N_{\mathrm{base}} = 487, \tag{80}$$

where N_{method} and N_{base} are the total detection counts after unlearning and for the original SD3-Turbo model, respectively. Retention is evaluated on benign MMA prompts [95] using LPIPS [103], DINO-I [64], DreamSim [30], and CLIP-I [43] relative to the original model's outputs; CLIP-T measures prompt–image alignment which is equivalent to CS.

At comparable LPIPS values, CePU with $\beta = 500$ achieves 78.85% DSR and 0.046 LPIPS, compared with 41.27% DSR and 0.042 LPIPS for DPO with $\beta = 500$, and 31.42% DSR and 0.049 LPIPS for DUO with $\beta = 100$. At stronger suppression settings, CePU with $\beta = 100$ achieves 97.13% DSR with 0.171 LPIPS, whereas DPO with $\beta = 100$ achieves 97.33% DSR with 0.267 LPIPS. These results support the applicability of CePU to the evaluated flow-matching backbone and demonstrate a favorable unlearning–retention trade-off at these operating points.

Table O: Nudity unlearning on SD3-Turbo. The five benchmark columns report nudity detections (lower is better). Total is their sum, and DSR is the percentage reduction relative to the original model. Retention metrics are evaluated on benign MMA prompts. DreamSim is displayed as a similarity score.

G Limitations

We view our scope and design choices as opportunities for further study of unlearning in FSD models. Our main experiments focus on two safety axes, celebrity identity and NSFW nudity, across DS-V7-LCM, DS-V8-LCM, and SD-Turbo. We additionally provide preliminary nudity-unlearning results on the MMDiT-based SD3-Turbo flow-matching model (Appendix F.6). These results support the applicability of CePU beyond the backbones used in our main experiments, but evaluation across additional flow-matching models, distillation procedures, and unlearning tasks is needed to establish broader generality. Other directions include broader harms (*e.g.*, violence, hate, or self-harm content), multilingual coverage beyond the three evaluated languages, code-mixed prompts, and simultaneous multi-concept unlearning. We rely on automatic evaluation metrics, including NudeNet [9], a celebrity face-ID classifier (Giphy celebrity detector) [6], LPIPS [103], CLIP score [43], DINOv2-based similarity [64], and DreamSim [30]. These metrics provide scalable, quantitative evaluation but are imperfect proxies for safety and utility and may exhibit biases. Complementing them with human evaluations and richer safety benchmarks remains valuable. We evaluate a limited grid of preference parameters β and retention weights λ, couple the learning rate to β, and fix other choices, including LoRA rank [45, 69]. Broader sensitivity analyses and automated hyperparameter selection across deployment settings remain future work. We also seek to extend our setup to continual unlearning [86, 37, 36, 80, 42].

H Broader Impacts

Text-to-image unlearning has the potential to improve the safe and responsible deployment of generative models by enabling the suppression of harmful, explicit, privacy-sensitive, or copyrighted content without requiring expensive retraining from scratch. Such methods may help mitigate misuse involving non-consensual imagery, public identity impersonation, unsafe content generation, and regulatory non-compliance, while providing a computationally efficient mechanism for post-deployment alignment of large generative models. However, these methods also introduce important societal risks. Selective concept removal may unintentionally suppress legitimate artistic, educational, or cultural expression, and poorly designed unlearning objectives may amplify demographic or representational biases. Furthermore, unlearning mechanisms could themselves be misused for targeted censorship or ideological suppression. Additionally, unlearning does not guarantee complete removal of harmful behavior, particularly under adversarial prompting or paraphrased queries. We therefore believe that text-to-image unlearning should be developed and deployed alongside careful evaluation, transparency, and human oversight.

NeurIPS Paper Checklist

1. **Claims**

   Question: Do the main claims made in the abstract and introduction accurately reflect the paper's contributions and scope?

   Answer: [Yes]

   Justification: We conduct all the necessary experiments in Section 3 and appropriately provide all the training and evaluation details for the experiments conducted to support our claims in Appendix E.

2. **Limitations**

   Question: Does the paper discuss the limitations of the work performed by the authors?

   Answer: [Yes]

   Justification: Appendix G discusses the limitations of this work

3. **Theory assumptions and proofs**

   Question: For each theoretical result, does the paper provide the full set of assumptions and a complete (and correct) proof?

   Answer: [Yes]

   Justification: All theoretical proofs and assumptions mentioned in the paper are discussed in detail in Appendix C.

4. **Experimental result reproducibility**

   Question: Does the paper fully disclose all the information needed to reproduce the main experimental results of the paper to the extent that it affects the main claims and/or conclusions of the paper (regardless of whether the code and data are provided or not)?

   Answer: [Yes]

   Justification: We conduct all the necessary experiments in Section 3 and appropriately provide all the training and evaluation details for the experiments conducted to support our claims in Appendix E.

5. **Open access to data and code**

   Question: Does the paper provide open access to the data and code, with sufficient instructions to faithfully reproduce the main experimental results, as described in supplemental material?

   Answer: [No]

   Justification: The code for paper will be released after seeking all the appropriate approvals.

6. **Experimental setting/details**

   Question: Does the paper specify all the training and test details (e.g., data splits, hyperparameters, how they were chosen, type of optimizer) necessary to understand the results?

   Answer: [Yes]

   Justification: All details are provided in Appendix E

7. **Experiment statistical significance**

   Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?

   Answer: [No]

   Justification: Repeated multi-seed evaluations were limited due to the high computational cost of post-training unlearning and large-scale generative evaluation on few-step diffusion models. To mitigate variance, we use fixed seeds, identical evaluation protocols, and consistent benchmark settings across all methods.

8. **Experiments compute resources**

   Question: For each experiment, does the paper provide sufficient information on the computer resources (type of compute workers, memory, time of execution) needed to reproduce the experiments?

Answer: [Yes]

Justification: See Appendix E

9. **Code of ethics**

   Question: Does the research conducted in the paper conform, in every respect, with the NeurIPS Code of Ethics https://neurips.cc/public/EthicsGuidelines?

   Answer: [Yes]

   Justification: The experiments use only synthetically generated images produced by publicly available open-weight generative models and do not involve private data collection or human subjects. The studied identities correspond to public figures already represented in existing generative models. The research is intended to improve safety and post-training alignment by mitigating identity-related misuse and memorization in text-to-image systems. Potential risks and societal impacts are discussed in the broader impact section.

10. **Broader impacts**

    Question: Does the paper discuss both potential positive societal impacts and negative societal impacts of the work performed?

    Answer: [Yes]

    Justification: See Appendix H.

11. **Safeguards**

    Question: Does the paper describe safeguards that have been put in place for responsible release of data or models that have a high risk for misuse (e.g., pre-trained language models, image generators, or scraped datasets)?

    Answer: [Yes]

    Justification: Our work studies safety-oriented unlearning for text-to-image generative models and is intended to mitigate harmful or identity-specific generation behaviors. The datasets used in this work are synthetically generated from publicly available open-weight models and do not contain scraped private data. Because the generated pairs and prompts may still enable misuse or facilitate reconstruction of sensitive concepts, we do not plan to release the complete generated datasets, full prompt collections, or resulting checkpoints publicly; representative prompts are included in the manuscript.

12. **Licenses for existing assets**

    Question: Are the creators or original owners of assets (e.g., code, data, models), used in the paper, properly credited and are the license and terms of use explicitly mentioned and properly respected?

    Answer: [Yes]

    Justification: All datasets, models, codebases, and external assets used in this work are appropriately credited, and their respective licenses and terms of use are respected.

13. **New assets**

    Question: Are new assets introduced in the paper well documented and is the documentation provided alongside the assets?

    Answer: [N/A]

14. **Crowdsourcing and research with human subjects**

    Question: For crowdsourcing experiments and research with human subjects, does the paper include the full text of instructions given to participants and screenshots, if applicable, as well as details about compensation (if any)?

    Answer: [N/A]

15. **Institutional review board (IRB) approvals or equivalent for research with human subjects**

    Question: Does the paper describe potential risks incurred by study participants, whether such risks were disclosed to the subjects, and whether Institutional Review Board (IRB) approvals (or an equivalent approval/review based on the requirements of your country or institution) were obtained?

Answer: [N/A]

16. **Declaration of LLM usage**

    Question: Does the paper describe the usage of LLMs if it is an important, original, or non-standard component of the core methods in this research? Note that if the LLM is used only for writing, editing, or formatting purposes and does *not* impact the core methodology, scientific rigor, or originality of the research, declaration is not required.

    Answer: [Yes]

    Justification: We acknowledge the use of LLM in creating certain parts of the textual part of the datasets following [50]. Apart from that the LLM is used only for writing, editing, or formatting purposes.
