## Abstract

Activation steering has emerged as a powerful approach for controlling large language models (LLMs), with prominent methods such as ActAdd, Directional Ablation, and Angular Steering relying on difference-in-means activations from contrastive prompts across layers. These differences are typically treated as candidate feature directions, later refined into optimal steering vectors or planes. In this work, we reinterpret these candidate directions as gradients of an underlying optimization problem. Building on this perspective, we propose Momentum Steering, a momentum-based framework for activation steering in LLMs. Unlike traditional difference-in-means methods, our framework generates a richer family of candidate directions through momentum updates, enabling more expressive steering. We first introduce a non-causal variant that accumulates difference-in-means signals via momentum, producing enhanced candidate directions. We then develop a causal variant, where future layer statistics are recursively influenced by previously applied momentum directions, explicitly modeling the causal effects of interventions on downstream activations. Momentum Steering is lightweight and modular, making it easily compatible with state-of-the-art steering methods. We empirically demonstrate that Momentum Steering delivers stronger, more robust, and more reliable behavioral control across diverse LLM families and benchmarks. The code is available at https://github.com/ltzryan/momentum_steering.

## 1 Introduction

Modern language and generative models expose internal representations that encode behaviors, concepts, and styles in surprisingly linear forms [11, 52, 39, 55, 51]. Activation steering leverages this structure by inserting carefully constructed steering vectors into hidden states at inference time, enabling control without retraining [43, 3, 56]. While different steering frameworks, such as Activation Addition (ActAdd) [53], Directional Ablation [3], and Angular Steering [56], vary in how interventions are applied, they share a common dependency, in which performance is fundamentally constrained by the quality of the underlying steering vectors.

A common practice is to derive these vectors via simple statistics, most often as difference-in-means [6] between contrastive prompt activations [3, 56, 43, 53, 1]. Sequential extensions [44] refine this idea by propagating steering layer by layer, but the underlying update remains memoryless, treating each layer independently. This design can overlook valuable structure across layers, producing unstable or underpowered feature directions, especially in deeper models or tasks requiring fine-grained control. Prior work has shown that layers in LLMs exhibit substantial coupling [58, 31,

40th Conference on Neural Information Processing Systems (NeurIPS 2026).

45], suggesting a coherent global structure in their representation space. Recent studies further demonstrate that interventions and analyses applied across multiple layers produce more reliable effects [3, 26, 56, 34], underscoring the importance of inter-layer dependencies for effective steering.

In this work we introduce Momentum Steering, an optimization-inspired approach to constructing steering vectors. Rather than treating each layer independently, Momentum Steering accumulates signals across layers through momentum updates, producing a richer family of candidate directions. This perspective connects steering vector construction to classical accelerated optimization, where momentum smooths trajectories and stabilizes convergence. We develop both non-causal and causal variants: the former aggregates difference-in-means statistics across layers, while the latter recursively incorporates the effect of previous interventions into future layer statistics.

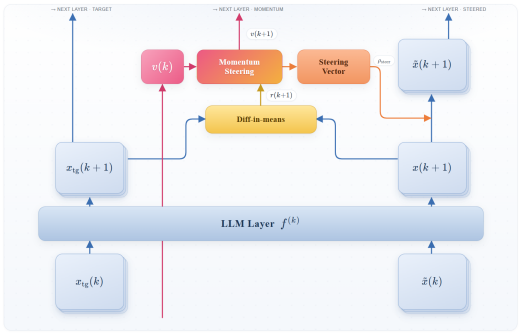

Figure 1: Illustration of Momentum Steering: To compute the steering direction, difference-in-means signals are accumulated across layers with a momentum buffer $\boldsymbol{v}(k)$ to form richer candidate directions.

Momentum Steering is lightweight, modular, and easily integrated into existing steering frameworks. Our experiments show that substituting difference-in-means with momentum-based updates yields stronger, more stable, and more reliable steering across a range of models, tasks, and benchmarks. By reinterpreting steering vector computation through the lens of optimization, we provide a simple yet powerful extension that enhances the effectiveness of activation steering methods.

## 2 Background

### 2.1 Decoder-only Transformers

We consider decoder-only Transformers [54] with $L$ layers. An input sequence of tokens $\boldsymbol{p} = [p_1, \ldots, p_n]$ is first mapped into embeddings $\boldsymbol{x}(1) = \text{Embed}(\boldsymbol{p}) \in \mathbb{R}^{n \times d}$. At each layer $k$, the residual state for token $i$ is updated by an attention sub-block followed by an MLP sub-block:

$$\boldsymbol{x}_{i,\text{attn}}(k) = \boldsymbol{x}_i(k) + \text{SelfAttn}^{(k)}(\text{Norm}(\boldsymbol{x}_i(k))),$$
$$\boldsymbol{x}_i(k+1) = \boldsymbol{x}_{i,\text{attn}}(k) + \text{MLP}^{(k)}(\text{Norm}(\boldsymbol{x}_{i,\text{attn}}(k))).$$

We denote the full layer update compactly as $\boldsymbol{x}^{(k+1)} = f^{(k)}(\boldsymbol{x}(k))$, where $f^{(k)}$ is the composition of the attention and MLP modules. After $L$ layers, the final residual stream $\boldsymbol{x}(L+1)$ is mapped to the vocabulary distribution through a decoder head. The residual stream $\{\boldsymbol{x}(k)\}_{k=1}^{L}$ is the primary object modified by activation steering.

### 2.2 Activation Steering

Activation steering modifies the hidden states at inference time to amplify or suppress specific features, without retraining. By setting $\boldsymbol{x}(1, \boldsymbol{p}) = \text{Embed}(\boldsymbol{p})$ and $\boldsymbol{r}(1) = 0$, these methods apply the steering vectors $\boldsymbol{r}(k)$ to the activation $\boldsymbol{x}(k)$, $k \in [K]$, at each layer via a steering function $\rho_{\text{steer}}$ as follows:

$$\boldsymbol{x}(k-1, \boldsymbol{p}) = \rho_{\text{steer}}(\boldsymbol{x}(k-1, \boldsymbol{p}), \boldsymbol{r}(k-1)), \ \boldsymbol{p} \in \mathcal{D}_{\text{source}} \tag{1}$$
$$\boldsymbol{x}(k, \boldsymbol{p}) = f^{(k)}(\boldsymbol{x}(k-1, \boldsymbol{p})), \ \boldsymbol{p} \in \mathcal{D}_{\text{source}} \cup \mathcal{D}_{\text{target}}, \tag{2}$$

where $\mathcal{D}_{\text{target}}$ and $\mathcal{D}_{\text{source}}$ are the sets of prompts that contain and do not contain the desired feature, respectively. Here, $\rho_{\text{steer}}$ is the steering function which defines the method of the intervention. Examples include:

- Activation Addition (ActAdd): $\boldsymbol{x}(k) \mapsto \boldsymbol{x}(k) + \gamma \boldsymbol{r}(k)$, shifting the hidden state in the feature direction.
- Directional Ablation (DirAblate): removes the component aligned with $\boldsymbol{r}(k)$, i.e., $\boldsymbol{x}(k) \mapsto \boldsymbol{x}(k) - \langle \boldsymbol{x}(k), \hat{\boldsymbol{r}}(k) \rangle \hat{\boldsymbol{r}}(k)$, where $\hat{\boldsymbol{r}}(k) = \boldsymbol{r}(k) / \|\boldsymbol{r}(k)\|_2$.

These frameworks differ in how interventions are applied, but they all depend fundamentally on the steering vectors $\boldsymbol{r}(k)$.

### 2.3 Constructing Steering Vectors

The most common method for constructing steering vectors is through *difference-in-means* [6]. Given two sets of prompts, a *source set* $D^{(\text{train})}_{\text{source}}$ where a feature is absent, and a *target set* $D^{(\text{train})}_{\text{target}}$ where it is present, the steering vector at layer $k$ is computed as $\boldsymbol{r}(k) = \boldsymbol{\mu}(k)_{\text{target}} - \boldsymbol{\mu}(k)_{\text{source}}$, where

$$\boldsymbol{\mu}(k)_{\text{target}} = \frac{1}{|D^{(\text{train})}_{\text{target}}|} \sum_{\boldsymbol{p} \in D^{(\text{train})}_{\text{target}}} \boldsymbol{x}(k, \boldsymbol{p}), \quad \boldsymbol{\mu}(k)_{\text{source}} = \frac{1}{|D^{(\text{train})}_{\text{source}}|} \sum_{\boldsymbol{p} \in D^{(\text{train})}_{\text{source}}} \boldsymbol{x}(k, \boldsymbol{p}).$$

Note that $D^{(\text{train})}_{\text{source}}$ and $D^{(\text{train})}_{\text{target}}$ here are used to compute the steering vectors $\boldsymbol{r}(k)$. These are different from $D_{\text{source}}$ and $D_{\text{target}}$ in Eqn. 1 and 2, which contain the prompts that need or do not need to be steered at inference time, respectively. This approach has proven effective in a wide range of applications, from reducing toxicity to controlling refusal behavior. However, it is limited by its reliance on static averages that ignore the dynamics of representation construction across layers. To address some of these limitations, sequential methods such as Mean-AcT [44] recompute difference-in-means vectors layer by layer after applying earlier interventions.

**Sequential Refinements.** Mean Activation Transport (Mean-AcT) [44] introduces sequential steering, where the intervention at a given layer conditions on prior interventions to capture multi-layer causal structure. Yet the steering vectors themselves remain layerwise and independently computed.

$$\boldsymbol{x}_i(k-1, \boldsymbol{p}) = \rho_{\text{steer}}(\boldsymbol{x}_i(k-1, \boldsymbol{p}), \boldsymbol{r}(k-1)), \quad \text{for } \boldsymbol{p} \in \mathcal{D}_{\text{source}} \tag{3}$$

$$\boldsymbol{x}_i(k, \boldsymbol{p}) = f_i^{(k)}(\boldsymbol{x}(k-1, \boldsymbol{p})), \quad \text{for } \boldsymbol{p} \in \mathcal{D}_{\text{source}} \cup \mathcal{D}_{\text{target}} \tag{4}$$

$$\boldsymbol{\mu}_{\text{target}}(k) = \frac{1}{|\mathcal{D}^{(\text{train})}_{\text{target}}|} \sum_{\boldsymbol{p} \in \mathcal{D}^{(\text{train})}_{\text{target}}} \frac{1}{|I_{\boldsymbol{p}}|} \sum_{i \in I_{\boldsymbol{p}}} \boldsymbol{x}_i(k, \boldsymbol{p}), \quad \boldsymbol{\mu}_{\text{source}}(k) = \frac{1}{|\mathcal{D}^{(\text{train})}_{\text{source}}|} \sum_{\boldsymbol{p} \in \mathcal{D}^{(\text{train})}_{\text{source}}} \frac{1}{|I_{\boldsymbol{p}}|} \sum_{i \in I_{\boldsymbol{p}}} \boldsymbol{x}_i(k, \boldsymbol{p})$$

$$\boldsymbol{r}(k) = \boldsymbol{\mu}_{\text{target}}(k) - \boldsymbol{\mu}_{\text{source}}(k). \tag{5}$$

## 3 Momentum Steering

In this section, we will formulate popular activation steering methods, such as ActAdd and Mean-AcT, as gradient descent updates. Based on this new interpretation, we propose Momentum Steering, a novel steering method that incorporates momentum updates into the computation of steering vectors.

### 3.1 Preliminaries: Momentum Acceleration for Gradient-Based Optimization

Momentum has long been used to accelerate gradient-based algorithms [40, 8, 47]. In optimization, the goal is to find a stationary point of a function $F(\boldsymbol{x}), \boldsymbol{x} \in \mathbb{R}^d$. Starting from $\boldsymbol{x}_0 \in \mathbb{R}^d$, gradient descent (GD) iterates as

$$\boldsymbol{x}(k+1) = \boldsymbol{x}(k) - \gamma \nabla F(\boldsymbol{x}(k)), \tag{6}$$

with step size $\gamma > 0$ [9]. GD and its variants are among the most widely used methods due to their dimension-independent convergence rates [8], low computational cost, and ease of parallelization, making them well suited to large-scale, high-dimensional problems [61, 63].

Despite these advantages, GD often converges slowly on ill-conditioned problems [10]. A standard remedy is to incorporate momentum [47] to accelerate convergence by accumulating past gradients:

$$\boldsymbol{v}(k) = \beta \boldsymbol{v}(k-1) - \nabla F(\boldsymbol{x}(k)), \quad \boldsymbol{x}(k+1) = \boldsymbol{x}(k) + \gamma \boldsymbol{v}(k), \tag{7}$$

where $\beta \geq 0$ is the momentum constant. This recursion can be written in the heavy-ball form [40]:

$$\begin{aligned} \boldsymbol{x}(k+1) &= \boldsymbol{x}(k) + \gamma(\beta \boldsymbol{v}(k-1) - \nabla F(\boldsymbol{x}(k))) \\ &= \boldsymbol{x}(k) - \gamma \nabla F(\boldsymbol{x}(k)) + \beta(\boldsymbol{x}(k) - \boldsymbol{x}(k-1)). \end{aligned} \tag{8}$$

By leveraging information from previous updates, momentum smooths the trajectory, reduces oscillations, and often achieves significantly faster convergence [40, 14].

### 3.2 Activation Steering from an Optimization Perspective

For a given LLM $\mathcal{M}$, let $\boldsymbol{x}_{tg}(t, \boldsymbol{p}_{tg})$ denote the activation corresponding to the target behavior at time $t$ when processing the input prompt $\boldsymbol{p}_{tg} \in \mathcal{D}_{\text{target}}$. Also, let $\boldsymbol{x}(t, \boldsymbol{p})$ denote the activation at time $t$ when processing the input prompt $\boldsymbol{p} \in \mathcal{D}_{\text{source}}$. Here, we use $\boldsymbol{x}(t, \boldsymbol{p})$ instead of the symmetric notation $\boldsymbol{x}_{src}(t, \boldsymbol{p}_{src})$ to simplify notation. Similarly, for notational brevity, in the derivation below, we write $\boldsymbol{x}_{tg}(t)$ and $\boldsymbol{x}(t)$ in place of the full forms $\boldsymbol{x}_{tg}(t, \boldsymbol{p}_{tg})$ and $\boldsymbol{x}(t, \boldsymbol{p})$, respectively. We are concerned with the following optimization problem for steering:

$$\min_{\boldsymbol{x} \in \mathcal{X}} J[\boldsymbol{x}], \quad J[\boldsymbol{x}] := \int_0^T D_h(\boldsymbol{x}(t), \boldsymbol{x}_{tg}(t)) dt. \tag{9}$$

Here, $\mathcal{X} = \{\boldsymbol{x} \in L^2([0, T]; \mathbb{R}^d) : J[\boldsymbol{x}] < \infty\}$ and $D_h(\boldsymbol{x}(t), \boldsymbol{x}_{tg}(t))$ is the Bregman divergence associated with function $h$ between $\boldsymbol{x}(t)$ and $\boldsymbol{x}_{tg}(t)$

$$D_h(\boldsymbol{x}(t), \boldsymbol{x}_{tg}(t)) = h(\boldsymbol{x}(t)) - h(\boldsymbol{x}_{tg}(t)) - \langle \nabla h(\boldsymbol{x}_{tg}(t)), \boldsymbol{x}(t) - \boldsymbol{x}_{tg}(t) \rangle, \tag{10}$$

where $h : \mathbb{R}^d \to \mathbb{R}$ is a strictly convex function with a Lipschitz gradient. The Bregman divergence $D_h(\boldsymbol{x}(t), \boldsymbol{x}_{tg}(t))$ measures the difference between the value of $h$ at point $\boldsymbol{x}(t)$ and the value of the first-order Taylor expansion of $h$ around point $\boldsymbol{x}_{tg}(t)$ evaluated at point $\boldsymbol{x}(t)$.

Since the integrand depends on $\boldsymbol{x}(t)$ but not on $\dot{\boldsymbol{x}}(t)$, the functional (Gateaux) derivative is the pointwise gradient of the integrand with respect to $\boldsymbol{x}(t)$:

$$\frac{\partial J}{\partial \boldsymbol{x}(t)} = \nabla h(\boldsymbol{x}(t)) - \nabla h(\boldsymbol{x}_{tg}(t)). \tag{11}$$

This yields the following time-varying gradient flow of $D_h(\cdot, \boldsymbol{x}_{tg}(t))$ for steering:

$$\frac{d\boldsymbol{x}(t)}{dt} = -\frac{\partial J}{\partial \boldsymbol{x}(t)} = \nabla h(\boldsymbol{x}_{tg}(t)) - \nabla h(\boldsymbol{x}(t)). \tag{12}$$

We then discretize Eqn. 12 using the Euler method [12, 15] with the step size $\gamma$. In particular, we begin the steering process at the point $\boldsymbol{x}(t_0)$ and set $t_k$ to be the $k$-th extraction point for $k \in [K]$. Likewise, for brevity, we write $\boldsymbol{x}(k)$ in place of $\boldsymbol{x}(t_k)$ and $\boldsymbol{x}_{tg}(k)$ in place of $\boldsymbol{x}_{tg}(t_k)$ for every $k$. We thus have

$$\begin{aligned} \tilde{\boldsymbol{x}}(k-1) &= \boldsymbol{x}(k-1) + \gamma(\nabla h(\boldsymbol{x}_{tg}(k-1)) - \nabla h(\boldsymbol{x}(k-1))) \\ &= \boldsymbol{x}(k-1) + \gamma \boldsymbol{r}(k-1) \end{aligned} \tag{13}$$

and the layer function $f^{(k)}$ in Eqn. 2 propagates the steered activation:

$$\boldsymbol{x}(k) = f^{(k)}(\tilde{\boldsymbol{x}}(k-1)). \tag{14}$$

We compare Eqn. 13 above with Eqn. 1. In Eqn. 1, by setting the ActAdd intervention $\rho_{\text{steer}}(\boldsymbol{x}(k-1, \boldsymbol{p}), \boldsymbol{r}(k-1)) = \boldsymbol{x}(k-1) + \gamma(\nabla h(\boldsymbol{x}_{tg}(k-1)) - \nabla h(\boldsymbol{x}(k-1)))$, we obtain the GD update in Eqn. 13. Here, we set the steering vector $\boldsymbol{r}(k-1)$ to the negative gradient, i.e., $\boldsymbol{r}(k-1) = \nabla h(\boldsymbol{x}_{tg}(k-1)) - \nabla h(\boldsymbol{x}(k-1))$. Note that different choices of function $h$ induce different steering vectors. Specifically, when choosing $h(\boldsymbol{x}) = \frac{1}{2}\|\boldsymbol{x}\|^2$, we obtain $\boldsymbol{r}(k-1) = \boldsymbol{x}_{tg}(k-1) - \boldsymbol{x}(k-1)$, and the gradient of $J$ is 1-Lipschitz in $\boldsymbol{x}$. While the unconstrained problem in Eqn. 9 is minimized at $\boldsymbol{x} = \boldsymbol{x}_{tg}$, we note that $\boldsymbol{x}_{tg}$ is unavailable at inference time, so we use the expected negative gradient of $J$ instead. The difference-in-means steering vectors in Section 2.3 correspond to the expected negative gradients over a source set of prompts $D_{\text{source}}^{(\text{train})}$ and a target set of prompts $D_{\text{target}}^{(\text{train})}$:

$$\boldsymbol{r}(k-1) = \frac{1}{|D_{\text{target}}^{(\text{train})}|} \sum_{\boldsymbol{p}_{tg} \in D_{\text{target}}^{(\text{train})}} \boldsymbol{x}_{tg}(k-1, \boldsymbol{p}_{tg}) - \frac{1}{|D_{\text{source}}^{(\text{train})}|} \sum_{\boldsymbol{p} \in D_{\text{source}}^{(\text{train})}} \boldsymbol{x}(k-1, \boldsymbol{p}). \tag{15}$$

Combining Eqn. 15 and the GD update in Eqn. 13 recovers ActAdd with difference-in-means steering vectors (with non-sequential steering) [53] and Mean-AcT (with sequential steering) [44].

We summarize the connections between activation steering and GD in the following proposition.

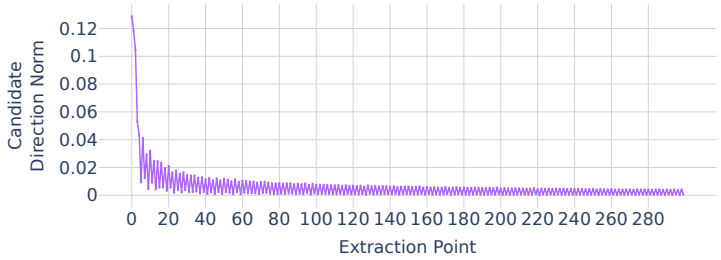

Figure 2: The norm of $\boldsymbol{r}(k)$ computed sequentially as in Equation 5 through a randomly initialized model.

**Proposition 3.1** (Gradient-derived Activation Steering)**.** *Let $J$ be the objective function defined in Eqn. 9 with associated function $h$, and let $\gamma, t_k$ and $\boldsymbol{x}(k)$ be defined as before Eqn. 13. For each $k \in [K]$, the ActAdd intervention with $\boldsymbol{r}(k-1)$ defined in Eqn. 13 satisfies:*

$$\tilde{\boldsymbol{x}}(k-1) = \boldsymbol{x}(k-1) - \gamma \left.\frac{\partial J}{\partial \boldsymbol{x}(t)}\right|_{t=t_{k-1}} \tag{16}$$

*and the steered activation is propagated through the layer function $f^{(k)}$ as in Eqn. 14. In particular, if $h(\boldsymbol{x}) = \frac{1}{2}\|\boldsymbol{x}\|^2$, empirical averaging over contrastive prompt sets gives the standard difference-in-means direction.*

*Remark* 3.2. Proposition 3.1 shows that a sequence of GD updates, each followed by the propagation through the respective layer function $f^{(k)}$, corresponds to an activation steering process in LLMs. Notably, popular methods such as ActAdd [53] and Mean-AcT [44] can be derived within this framework. However, Proposition 3.1 does not claim that all activation steering methods are reducible to GD updates, nor that the combined updates in Eqns. 13 and 14 monotonically decrease $J$.

*Remark* 3.3. Our optimization framework for steering can be easily extended by introducing a new objective function $J[\boldsymbol{x}]$ or by using advanced optimization algorithms.

**Empirical Evidence:** We provide empirical support for the connection between activation steering and GD. Specifically, for a set of contrastive prompts, we compute candidate steering vectors $\boldsymbol{r}(k)$ sequentially from a randomly initialized model (details in Appendix A). Figure 2 shows that the norm $\|\boldsymbol{r}(k)\|_2$ steadily decreases toward zero as $k$ increases. This aligns with the GD interpretation, in which the gradient norm, represented here by $\|\boldsymbol{r}(k)\|_2$, typically diminishes with increasing iterations.

### 3.3 Momentum Steering

#### 3.3.1 Overview

GD is widely adopted for its dimension-independent convergence, low computational cost, and parallel efficiency, making it well suited for large-scale, high-dimensional problems. However, it converges slowly on ill-conditioned objectives [10]. As activation steering methods such as ActAdd and Mean-AcT can be viewed through the GD lens established in Proposition 3.1, they may share analogous limitations. Motivated by this, we introduce momentum into the computation of feature directions (steering vectors) and propose *Momentum Steering*. Rather than using raw difference-in-means as candidates, we accumulate them over layers through a momentum buffer. Leveraging the acceleration of momentum methods, Momentum Steering generally achieves more effective steering.

#### 3.3.2 Calculating the Steering Direction via Momentum

The steering vector in Momentum Steering is set to the momentum buffer $\boldsymbol{v}$ in Eqn. 7. Specifically, setting $\boldsymbol{v}(0) = 0$, at each extraction point $k$, we compute the momentum steering vector $\boldsymbol{v}(k)$ as follows:

$$\boldsymbol{v}(k) = \beta \boldsymbol{v}(k-1) + \boldsymbol{r}(k), \qquad k = 1, \ldots, K, \tag{17}$$

where $\beta \geq 0$ is the momentum coefficient. Here, $\boldsymbol{r}$ can be computed non-sequentially or sequentially as discussed in Section 2.3.

We define Momentum Steering in the following definition.

**Definition 3.4** (Momentum Steering)**.** Consider a large language model composed of layers $\{f^{(k)}\}_{k=1}^{K}$ with steering function $\rho_{\text{steer}}$. Initialize $\boldsymbol{v}(0) = 0$ and $\boldsymbol{r}(1) = 0$. Then, Momentum Steering constructs the steering vectors by the recursive update

$$\boldsymbol{v}(k) = \beta \boldsymbol{v}(k-1) + \boldsymbol{r}(k), \qquad k = 1, \ldots, K, \tag{18}$$

where, for non-sequential steering,

$$\boldsymbol{r}(k) = \mathbb{E}_{\boldsymbol{q}_{tg} \in \mathcal{D}^{(\text{train})}_{\text{target}}}[\boldsymbol{x}_{tg}(k, \boldsymbol{q}_{tg})] - \mathbb{E}_{\boldsymbol{q} \in \mathcal{D}^{(\text{train})}_{\text{source}}}[\boldsymbol{x}(k, \boldsymbol{q})],$$

and, for sequential steering,

$$\boldsymbol{x}(k) = f^{(k)}\left(\rho_{\text{steer}}\big(\boldsymbol{x}(k-1), \boldsymbol{v}(k-1)\big)\right), \quad \boldsymbol{r}(k) = \mathbb{E}_{\boldsymbol{q}_{tg} \in \mathcal{D}^{(\text{train})}_{\text{target}}}[\boldsymbol{x}_{tg}(k, \boldsymbol{q}_{tg})] - \mathbb{E}_{\boldsymbol{q} \in \mathcal{D}^{(\text{train})}_{\text{source}}}[\boldsymbol{x}(k, \boldsymbol{q})].$$

### 3.4 Beyond Momentum: Steering with Advanced Optimizers

Our Momentum Steering can be easily generalized to other advanced momentum-based optimization methods. In this section, we present a variant of Momentum Steering derived from Adam [21].

Adam leverages the moving average of historical gradients and entry-wise squared gradients to accelerate gradient dynamics. We use Adam to accelerate Eqn. 13 and obtain the following Adam Steering.

**Definition 3.5** (Adam Steering)**.** Consider a large language model composed of layers $\{f^{(k)}\}_{k=1}^{K}$ with steering function $\rho_{\text{steer}}$. Initialize $\boldsymbol{p}(0) = 0$, $\boldsymbol{m}(0) = 0$, and $\boldsymbol{r}(1) = 0$. Let $\beta_1, \beta_2 \in [0, 1)$ and choose a small constant $\epsilon > 0$ (e.g., $\epsilon = 10^{-8}$). Then, Adam Steering constructs the steering vectors by the recursive update

$$\boldsymbol{p}(k) = \beta_1 \boldsymbol{p}(k-1) + (1-\beta_1)\boldsymbol{r}(k) \qquad \boldsymbol{m}(k) = \beta_2 \boldsymbol{m}(k-1) + (1-\beta_2)\boldsymbol{r}(k) \odot \boldsymbol{r}(k)$$

$$\widehat{\boldsymbol{p}}(k) = \boldsymbol{p}(k)/(1-\beta_1^k) \qquad \widehat{\boldsymbol{m}}(k) = \boldsymbol{m}(k)/(1-\beta_2^k)$$

$$\boldsymbol{v}(k) = \widehat{\boldsymbol{p}}(k)/(\sqrt{\widehat{\boldsymbol{m}}(k)} + \epsilon), \qquad k = 1, \ldots, K,$$

where for non-sequential steering,

$$\boldsymbol{r}(k) = \mathbb{E}_{\boldsymbol{q}_{tg} \in \mathcal{D}^{(\text{train})}_{\text{target}}}[\boldsymbol{x}_{tg}(k, \boldsymbol{q}_{tg})] - \mathbb{E}_{\boldsymbol{q} \in \mathcal{D}^{(\text{train})}_{\text{source}}}[\boldsymbol{x}(k, \boldsymbol{q})],$$

and for sequential steering,

$$\boldsymbol{x}(k) = f^{(k)}\left(\rho_{\text{steer}}\big(\boldsymbol{x}(k-1), \boldsymbol{v}(k-1)\big)\right), \quad \boldsymbol{r}(k) = \mathbb{E}_{\boldsymbol{q}_{tg} \in \mathcal{D}^{(\text{train})}_{\text{target}}}[\boldsymbol{x}_{tg}(k, \boldsymbol{q}_{tg})] - \mathbb{E}_{\boldsymbol{q} \in \mathcal{D}^{(\text{train})}_{\text{source}}}[\boldsymbol{x}(k, \boldsymbol{q})].$$

*Remark* 3.6 (Offline Computation). The steering vectors $\boldsymbol{v}(k)$ in Momentum Steering (Definition 3.4) and Adam Steering (Definition 3.5) are computed entirely offline. No additional computation is incurred during inference.

**Theoretical Guarantees:** We provide a stability analysis of Momentum Steering in Appendix D.

## 4 Experiments

We evaluate Momentum and Adam Steering across a comprehensive set of experiments across two datasets. First, following the Angular Steering framework [56], in Section 4.1 we evaluate our method on the jailbreaking task, which aims to override a model's default refusal behavior and induce harmful outputs. We further study how varying dataset size influences steering effectiveness in Section 4.2. We also extend our evaluation to the sequential setting of Mean-AcT and Linear-AcT [44] in Section 4.3. Finally, we study the effect of the momentum coefficient $\beta$ in Section 4.4. All experiments are conducted on 4 $\times$ NVIDIA H100 GPUs, each with 96GB of memory.

### 4.1 Regulating the Steering Effect on a Jailbreaking Task

**Experiment Settings:** We follow the settings proposed in Angular Steering [56], replacing its difference-in-means candidate directions with our two momentum-accelerated variants: Momentum Steering ($\beta = 0.99$) and Adam Steering ($\beta_1 = 0.9$, $\beta_2 = 0.999$). We utilize an $80\%$ split (416 samples) of the prompts ADVBENCH [65] dataset as our harmful dataset and a random sample of 512 harmless prompts from the ALPACA [48] dataset to compute our refusal directions. We evaluate the performance of the steering behavior on the remaining $20\%$ (104 samples) of the ADVBENCH dataset. We use the open-source HARMBENCH classifier [30] to classify if the generations are harmful, yielding 1 if so and 0 otherwise.

We test our method on a wide array of model families: Qwen2.5 [60], Gemma2 [13], Llama3 [27], where the model size ranges from 3B to 14B parameters. We also include a more safety-aligned version of Gemma2 [41] in our experimental setup. Lastly, we evaluate our methods on

Table 1: Performance of our methods in a non-sequential setting against the Baseline on the Jailbreaking Task and tinyBenchmarks [28]. AS indicates Angular Steering [56]. Higher is better. Best ASR is bolded.

the tinyBenchmarks [28], to assess the effect of our methods on the model's general language performance relative to the baseline. The results from our experiments are compiled in Tables 1, 2 and 3, and the baseline in those tables indicates using only difference-in-means non-sequentially to compute the steering plane required for angular steering.

**Results:** We first evaluate the attack success rates when the refusal directions are computed non-sequentially. From Table 1, we observe that using momentum or Adam leads to improvements over the baseline in the majority of configurations. The greatest difference comes from the Gemma2-9B-Instruct model, where the baseline struggles the most, achieving a success rate of less than $10\%$. Here, both momentum and Adam configurations achieve significant performance gains, surpassing $30\%$. This provides evidence that simply considering the velocities or moments non-sequentially can already lead to a meaningful improvement in the steering effect.

We compare sequential vs. non-sequential steering (Table 2). Here, we observe that sequential steering yields further gains in many settings, with improvements observed across multiple model families. For example, on Qwen2.5-7B-Instruct, all sequential configurations improve over their non-sequential counterparts, with sequential Momentum (AA) and Adam (AA) raising ASR from $75.96\%$ and $78.85\%$ to $84.62\%$ and $88.46\%$ respectively. This shows that accounting for activation causality through sequential steering can further strengthen the steering effect.

We compare all different configurations of our methods against the baseline on the safer aligned version of Gemma2-9B-Instruct. From Table 3, we observe that all configurations significantly outperform the baseline, which achieves a success rate of less than $2\%$. Thus, this shows that our methods remain effective even against stronger safety alignment. Finally, we observe that the tinyBenchmark scores of our configurations are mainly consistent with the baseline across all tables, indicating no significant deterioration in general model utility.

### 4.2 Experiments on Smaller Dataset Sizes

A natural question is whether the steering behavior of Momentum Steering is sensitive to the size of the dataset used to compute the momentum buffers. We therefore investigate this by varying the size of the dataset used to sequentially compute the refusal directions using momentum and observe how the resulting buffers affect the steering behavior.

**Experiment Settings:** We perform the same experiment on the jailbreaking task as described in Section 4.1. However, we now reduce the sample size of the harmful and harmless datasets respectively used to compute the refusal directions. We use sizes of 8, 16, 32, and 64 on the harmful and harmless datasets respectively, and we use momentum-based configurations where the refusal directions are computed sequentially. Lastly, we utilize models from the Gemma2 family in this experiment, as we have seen the significant improvements that using momentum-based configurations have on the steering effect. The results of this experiment can be found in Figure 3.

Table 2: Performance of our methods in both sequential and non-sequential settings. The Seq. column indicates sequential steering, and AS, (AA) and (DA) denote Angular Steering with ActAdd and Directional Ablation respectively.

sizes. Thus, this serves as evidence that even with a reduced dataset size, using momentum to sequentially compute the refusal direction will still yield the desired steering behavior.

### 4.3 Experiments on Toxicity Mitigation

**Experiment Settings:** We follow the experimental setup proposed in [44]. In our method, we replace the difference-in-means used in Mean-AcT with its accumulation across layers computed via momentum updates, which we refer to as Momentum-AcT. However, since Mean-AcT considers the mean over all tokens across all prompts (instead of just the final token in every prompt as in Angular Steering), to be consistent, Momentum-AcT considers the difference-in-means computed through Mean-AcT, when computing the momentum updates. We obtain the completed generations of 1000 prompts from RealToxicityPrompts (RTP), and we evaluate the toxicity via a ROBERTA-based classifier [46]. In addition, we also measure toxicity by querying a Llama3-8B-Instruct model in a zero-shot manner, where the Llama3-8B-Instruct model is an LLM-as-a-judge [62]. To test the model's general LLM utility, we also report the following metrics: (i) the perplexity (PPL) on a fixed set of 20K Wikipedia sentences, (ii) the PPL of outputs generated by the intervened model measured using Mistral-7B [20] and (iii) MMLU 5-shot accuracy [17]. Finally, we perform the experiment on Gemma2-2B and Llama3-8B.

**Results:** From Table 4, we observe that sequential momentum steering reduces the toxicity by up to 7.5 times in Gemma2-2B, and up to 6.8 times with Llama3-8B. This outperforms the baseline of Mean-AcT and Linear-AcT, in both the sequential and non-sequential setting. Furthermore, sequential momentum steering also yields the lowest toxicity across both models on the 0-shot toxicity metric. Finally, we observe that, similar to Mean-AcT and Linear-AcT, sequential steering with momentum has little effect on the PPL and MMLU scores.

### 4.4 Ablation Study on the Momentum Coefficient

In the jailbreaking task in Section 4.1, we used a momentum coefficient of $\beta = 0.99$ for all configurations of Momentum Steering. To assess the importance of the momentum coefficient, we perform an ablation study and vary the value of $\beta$ between 0 and 0.99. Here, setting $\beta = 0$ implies that no momentum is used. We evaluate how the different choices of the momentum coefficient $\beta$ affect the attack success rate of Momentum Steering on Qwen2.5-7B-Instruct, Llama3.2-3B-Instruct and Gemma2-9B-Instruct, and the results are compiled in Table 5.

We can observe that for Qwen2.5-7B-Instruct, the highest attack success rate varies across configurations, with non-sequential Momentum Steering peaking at $\beta = 0.75$, while the sequential steering with ActAdd and Directional Ablation peak at $\beta = 0.95$ and $\beta = 0.9$ respectively. For Llama3.2-3B-Instruct, the non-sequential and sequential steering with directional ablation configurations peak at $\beta = 0.95$ and $\beta = 0.9$ respectively, with performance generally increasing as we increase $\beta$ before dipping slightly at higher values. As for sequential steering with ActAdd, we observe an increasing trend, peaking at $\beta = 0.99$. For Gemma2-9B-Instruct, the attack success rate for all configurations is highest at $\beta = 0.95$. Furthermore, the attack success rates generally increase as we increase $\beta$ towards 0.95, before dipping slightly at 0.99.

Table 5: Ablation study on the different choices of momentum coefficient $\beta$ following the experiments in Section 4.1 performed on Qwen2.5-7B-Instruct, Llama3.2-3B-Instruct and Gemma2-9B-Instruct. We report ASR for each $\beta$. The best score within each row is bolded. Setting $\beta = 0$ corresponds to no momentum; experiments in Section 4.1 use $\beta = 0.99$.

| Method | $\beta = 0$ | $\beta = 0.5$ | $\beta = 0.75$ | $\beta = 0.9$ | $\beta = 0.95$ | $\beta = 0.97$ | $\beta = 0.99$ |
|---|---|---|---|---|---|---|---|
| **Qwen2.5-7B-Instruct** | | | | | | | |
| AS + Mom. | 77.88 | 76.92 | **81.73** | 75.00 | 77.88 | 77.88 | 75.96 |
| AS + Mom. (AA) | 71.15 | 81.73 | 85.58 | 86.54 | **89.42** | 87.50 | 84.62 |
| AS + Mom. (DA) | 46.15 | 81.73 | 81.73 | **82.69** | 78.85 | 81.73 | 81.73 |
| **Llama3.2-3B-Instruct** | | | | | | | |
| AS + Mom. | 75.00 | 75.00 | 79.81 | 85.58 | **88.46** | 83.65 | 86.54 |
| AS + Mom. (AA) | 25.96 | 55.77 | 50.96 | 65.38 | 66.35 | 70.19 | **75.00** |
| AS + Mom. (DA) | 88.46 | 90.38 | 88.46 | **91.35** | **91.35** | 90.38 | 88.46 |
| **Gemma2-9B-Instruct** | | | | | | | |
| AS + Mom. | 7.69 | 9.62 | 26.92 | 40.38 | **46.15** | 45.19 | 40.38 |
| AS + Mom. (AA) | 20.19 | 21.15 | 42.31 | 47.12 | **50.00** | 43.27 | 42.31 |
| AS + Mom. (DA) | 19.23 | 17.31 | 32.69 | 44.23 | **50.96** | 44.23 | 41.35 |

Finally, we observe that there are certain configurations where choices of $\beta > 0$ yield lower attack success rates compared to when no momentum ($\beta = 0$) is used. However, even in those cases, we observe that choosing a sufficiently large $\beta$ will generally yield improvements over the case without momentum. The combination of observations above suggests that having a high momentum coefficient is generally beneficial in improving the attack success rate, but careful tuning around those high values might be required to obtain the best performance.

## 5 Related Work

**Activation Steering:** A common hypothesis in mechanistic interpretability is that features, whether representing behaviors or abstract concepts, tend to align with nearly orthogonal directions in the activation space [39, 7, 11, 51]. From this perspective, activation steering operates by intervening in a model's hidden states at inference, selectively amplifying or dampening particular features [56, 3, 4, 22, 25, 29, 1, 53, 64, 49, 34]. In practice, many recent methods implement this strategy by explicitly constructing feature-aligned directions termed *steering vectors* $\boldsymbol{r}$, which provide handles for manipulating internal representations. A standard way of obtaining these vectors is to compute the layerwise difference between the average activations of a model on two contrasting datasets (for example, harmful vs. harmless prompts). This *difference-in-means* approach [43] has been shown across several studies to reliably recover meaningful feature directions [53, 43, 56, 2].

**Momentum in Deep Learning Models:** Momentum has inspired diverse DNN architectures [57]. A momentum-driven moving-average encoder enables large, stable dictionaries for contrastive unsupervised learning [16], while accelerated algorithms such as FISTA [5] motivate unfolded sparse-coding networks [32]. Momentum has also been embedded in ResNet and DenseNet [24], RNNs [36], neural differential equations [59, 35], transformers [37], and sparse mixtures of experts [50, 33], and used to accelerate and stabilize state space models [38].

## 6 Concluding Remarks

We reframe the construction of steering directions as an optimization problem, providing a principled view of difference-in-means directions and extending them with momentum dynamics. This leads to Momentum Steering, a lightweight and modular framework that expands the space of steering directions through momentum accumulation and recursive causal updates. Experiments show that Momentum Steering improves reliability and performance over existing methods while remaining compatible with state-of-the-art steering techniques. These results identify momentum as a useful inductive bias for scalable LLM control. While we observe strong empirical performance with Momentum Steering, a limitation of our work is that the gains are inconsistent across model families and remain sensitive to $\beta$, requiring careful per-model tuning to achieve the best results. We leave a principled strategy for hyperparameter selection to future work.

## A Experiment Settings Related to the Randomly Initialized Model

In this section, we provide more details regarding the experiment pertaining to the randomly initialized toy transformer model. We first provide the relevant architectural details in Table 6.

We note that the dimension of the model here was kept small to account for the large volume of layers. The contrastive dataset used for this experiment is identical to the curated harmful and harmless datasets described in Section 4.1. Finally, we note that we are following the approach from [56] in extracting the activations required (at the LayerNorm of each Attention and MLP Block) for computing the steering vectors. This results in the 300 extraction points shown in Figure 2.

## B Evaluation on Additional Models

In addition to the models run in Section 4.1, we further evaluate Momentum and Adam Steering on additional models from the same family. In particular, we evaluate on Qwen2.5-3B-Instruct, Qwen2.5-32B-Instruct, Llama3.1-8B-Instruct and Gemma2-27B-Instruct. The settings here are almost identical to the previous settings described in Section 4.1, but the moment coefficients of Adam Steering on Gemma2-27B-Instruct are switched to $\beta_1 = 0.999$ and $\beta_2 = 0.5$, since we observed that using the original coefficients ($\beta_1 = 0.9$, $\beta_2 = 0.999$) here exhibits subpar performance. We compile the results in Table 7.

We see that the results here mostly coincide with the observations made in Section 4.1. Here, we observe that configurations involving both momentum and Adam mostly outperform their baseline

Table 6: Relevant architectural details of the randomly initialized Transformer model. $hidden_size$ represents the size of the hidden layer in each MLP block, and $d_model$ represents the dimensions of the activations.

counterparts. Once again, we see a significant improvement on the Gemma2-27B-Instruct model, achieving up to 71% attack success rate with Momentum Steering as compared to the 5% achieved by the baseline. For the same model, we also see significant performance gains when using Adam Steering, but we note that we had to modify the moment coefficients from the original. Thus, we posit that fine-tuning of the moment coefficients might be necessary to obtain the best possible performance.

## C Extended Ablation Study on the Momentum Coefficient

Following the additional results reported in Appendix B, we also extend our ablation study in Section 4.4 to include observations of the effect varying the momentum coefficient $\beta$ has on the attack success

rate of Gemma2-27B-Instruct. As in Section 4.4, we vary the value of $\beta$ between 0 and 0.99, and the attack success rates are recorded in Table 8.

Similar to the ablation study on Gemma2-9B-Instruct, the attack success rate for both configurations of sequential Momentum Steering on Gemma2-27B-Instruct is highest at $\beta = 0.95$. The attack success rates generally increase as we increase $\beta$ towards 0.95, before dropping at 0.99. As for non-sequential Momentum Steering in particular, the increasing trend extends further beyond 0.95, and we observe the performance peaks exactly when $\beta = 0.99$. Finally, consistent with the observations in Section 4.4, there are choices of $\beta > 0$ that yield lower attack success rates compared to when no momentum ($\beta = 0$) is used. Here, this occurs for sequential Momentum Steering with Directional Ablation at $\beta = 0.75$. However, choosing a sufficiently large $\beta$ ($\beta \geq 0.9$) still provides an improvement compared to when there is no momentum.

# D Stability Analysis of Momentum Steering

In this section, we perform stability analysis on our Momentum Steering method. For tractability, we omit the layer functions $f^{(k)}$ within our analysis. We rewrite Momentum Steering in its equivalent heavy-ball formulation (Eqn. 8) as:

$$\boldsymbol{x}(k+1) = \boldsymbol{x}(k) + \gamma \boldsymbol{v}(k) = \boldsymbol{x}(k) + \gamma \boldsymbol{r}(k) + \beta(\boldsymbol{x}(k) - \boldsymbol{x}(k-1)) \tag{19}$$

For simplicity, let us assume $h(\boldsymbol{x}) = \frac{1}{2}\|\boldsymbol{x}\|_2^2$. Thus, $\boldsymbol{r}(k)$ can be written as:

$$\boldsymbol{r}(k) = \boldsymbol{x}_{tg}(k) - \boldsymbol{x}(k) \tag{20}$$

Substituting Eqn. 20 into the heavy-ball formulation yields

$$\begin{aligned} \boldsymbol{x}(k+1) &= \boldsymbol{x}(k) + \gamma(\boldsymbol{x}_{tg}(k) - \boldsymbol{x}(k)) + \beta(\boldsymbol{x}(k) - \boldsymbol{x}(k-1)) \\ &= (1 + \beta - \gamma)\boldsymbol{x}(k) - \beta \boldsymbol{x}(k-1) + \gamma \boldsymbol{x}_{tg}(k) \end{aligned} \tag{21}$$

By considering each coordinate $\boldsymbol{x}(k, n)$ individually, the coordinate-wise update rule can be given as:

$$\boldsymbol{x}(k+1, n) = (1 + \beta - \gamma)\boldsymbol{x}(k, n) - \beta \boldsymbol{x}(k-1, n) + \gamma \boldsymbol{x}_{tg}(k, n) \tag{22}$$

Equivalently, we express the recurrence in matrix form:

$$\underbrace{\begin{pmatrix} \boldsymbol{x}(k, n) \\ \boldsymbol{x}(k+1, n) \end{pmatrix}}_{y(k+1)} = \underbrace{\begin{pmatrix} 0 & 1 \\ -\beta & 1 + \beta - \gamma \end{pmatrix}}_{A} \underbrace{\begin{pmatrix} \boldsymbol{x}(k-1, n) \\ \boldsymbol{x}(k, n) \end{pmatrix}}_{y(k)} + \underbrace{\begin{pmatrix} 0 \\ \gamma \boldsymbol{x}_{tg}(k, n) \end{pmatrix}}_{b(k)} \tag{23}$$

For compact notation, let us define $y(k), b(k)$ and $A$ as annotated in the underbraces in Eqn. 23. We can thus rewrite Eqn. 23 as:

$$y(k+1) = Ay(k) + b(k) \tag{24}$$

We can assume that $y(0)$ is known. The eigenvalues of the update matrix $A$ play a significant role in determining if $y(k)$ converges. In particular, we would like the eigenvalues of $A$ to lie strictly inside the unit circle in the complex plane. This condition yields bounds on the admissible ranges of $(\gamma, \beta)$ and we show them explicitly in Lemma D.1.

**Lemma D.1.** *Consider the update matrix* $A = \begin{pmatrix} 0 & 1 \\ -\beta & 1 + \beta - \gamma \end{pmatrix}$ *given in Eqn. 23 and Eqn. 24. Then, the spectral radius* $\rho(A) < 1$ *if and only if we have* $\beta \in (-1, 1)$ *and* $\gamma \in (0, 2 + 2\beta)$.

*Proof.* Let us first consider the characteristic polynomial of $A$, given by:

$$\begin{aligned} p(\lambda) &= \det(A - \lambda I) \\ &= -\lambda((1 + \beta - \gamma) - \lambda) - (-\beta) \\ &= \lambda^2 - (1 + \beta - \gamma)\lambda + \beta \end{aligned} \tag{25}$$

We note that $\rho(A) < 1$ is equivalent to the roots of the polynomial lying inside the unit circle, and we can use Jury's Test [19] to assist in determining necessary and sufficient conditions on $\beta$ and $\gamma$. For an arbitrary quadratic polynomial given by $f(z) = z^2 + a_1 z + a_2$, the Jury's test states that the

necessary conditions for the roots to lie in the unit circle are that $f(1) > 0$ and $(-1)^2 f(-1) > 0$, and the sufficient conditions are that we have $1 > |a_2|$ and $|1 + a_2| > |a_1|$.

Comparing this with $p$, we can observe that the sufficient conditions for $\beta$ and $\gamma$ are that $\beta \in (-1, 1)$ and $\gamma \in (0, 2 + 2\beta)$. This is because under these choices, we have $|\beta| < 1$ and $|1 + \beta - \gamma| < |1 + \beta|$, and these are the sufficient conditions for the roots of $p$ to lie in the unit circle. We can also observe that the necessary conditions here are that $p(1) > 0$ and $(-1)^2 p(-1) = p(-1) > 0$, which are equivalent to $\gamma \in (0, 2 + 2\beta)$. To complete the proof, we will now show that $\beta \in (-1, 1)$ is also a necessary condition, and we do this by noticing that $\beta = \lambda_1 \lambda_2$, where $\lambda_1$ and $\lambda_2$ are roots of the polynomial. Since $\rho(A) < 1$, we must have $|\lambda_1|, |\lambda_2| < 1$ and by extension, $|\beta| < 1$. This is equivalent to $\beta \in (-1, 1)$, thus completing the proof as desired. □

As the update equation given in Eqn. 24 has a time-varying bias in $b(k)$, an intuitive condition for the convergence of $y(k)$ would be if the bias converges asymptotically. Thus, in addition to the eigenvalues lying strictly inside the unit circle in the complex plane as mentioned in Lemma D.1, if the bias term converges, we prove that our steering method converges as well in Theorem D.2, and we provide the explicit solution it converges to.

**Theorem D.2** (Convergence of Momentum Steering)**.** *Suppose that $b(k)$ in Eqn. 24 converges to some $b^*$ (equivalently, $\boldsymbol{x}_{tg}(k, n)$ converges to some $\boldsymbol{x}^*_{tg}(n)$ in Eqn. 23). If $\beta \in (-1, 1)$ and $\gamma \in (0, 2+2\beta)$, then $y(k)$ in the dynamics defined by Eqn. 24 converges to $y^*$, where $y^* = (I - A)^{-1} b^*$.*

*Proof.* We first note that when $\beta \in (-1, 1)$ and $\gamma \in (0, 2 + 2\beta)$, by Lemma D.1, we have that $\rho(A) < 1$. From Gelfand's formula [18], if $\rho(A) < 1$, we have the following identity:

$$\rho(A) = \lim_{k \to \infty} \|A^k\|^{\frac{1}{k}} \tag{26}$$

for any submultiplicative matrix norm (such as the $L_2$ norm). Choosing an $\alpha$ such that we have $\rho(A) < \alpha < 1$, by considering a small neighborhood around $\rho(A)$, we can find $K$ such that for $k \geq K$, $\|A^k\|^{\frac{1}{k}} < \alpha < 1$. Since we have $\|A^k\|^{\frac{1}{k}} \geq 0$ for all $k$, we thus observe that $\|A^k\| \leq \alpha^k$ for $k \geq K$, and we thus find a positive constant $M$ such that $\|A^k\| \leq M\alpha^k$ for all positive integers $k$.

Now, with respect to the relation in Eqn. 24, by writing it as a telescoping sum, we have:

$$y(k) = A^k y(0) + \sum_{j=0}^{k-1} A^j b(k - 1 - j) \tag{27}$$

Observe that since $\rho(A) < 1$, $(I - A)^{-1}$ exists and we have:

$$(I - A)^{-1} = \sum_{r=0}^{\infty} A^r \tag{28}$$

and thus we have that:

$$(I - A)^{-1} b^* = \sum_{r=0}^{\infty} A^r b^* \tag{29}$$

Fix $\epsilon > 0$ and now consider $\|y(k) - y^*\|$, we thus have:

$$\begin{aligned}
\|y(k) - y^*\| &= \left\| y(k) - \sum_{r=0}^{\infty} A^r b^* \right\| \\
&= \left\| A^k y(0) + \sum_{j=0}^{k-1} A^j b(k - 1 - j) - \sum_{r=0}^{\infty} A^r b^* \right\| \\
&= \left\| A^k y(0) + \sum_{j=0}^{k-1} A^j (b(k - 1 - j) - b^*) - \sum_{r=k}^{\infty} A^r b^* \right\| \\
&\leq \|A^k\| \|y(0)\| + \sum_{j=0}^{k-1} \|A^j\| \|(b(k - 1 - j) - b^*)\| + \sum_{r=k}^{\infty} \|A^r\| \|b^*\|
\end{aligned} \tag{30}$$

For the first term, observe that since $\|A^k\| \leq M\alpha^k$ for all $k$ and $\alpha < 1$, we have $\|A^k\| \to 0$ as $k \to \infty$. Thus, we can always choose $N_1$ such that $k > N_1$, we have $\|A^k\| < \frac{\epsilon}{3\|y(0)\|}$.

For the second term, once again by noticing the inequality on $\|A^k\|$, we have that:

$$\begin{aligned} \sum_{k=0}^{\infty} \|A^k\| &\leq M \sum_{k=0}^{\infty} \alpha^k \\ &= \frac{M}{1-\alpha} \end{aligned} \tag{31}$$

Furthermore, since $b(k)$ is convergent, we can confirm that $b(k)$ is bounded. Let $B$ be an upper bound on $\|b(k)\|$ for all $k$. Since $\alpha < 1$, let us choose $N$ such that we have $\alpha^N \leq \frac{(1-\alpha)\epsilon}{12BM}$. Then, once again since $b(k)$ is convergent, we can choose $N_2 > N$ such that for all $k > N_2$, $\|b(k-N) - b^*\| < \frac{(1-\alpha)\epsilon}{6M}$. Now, for $k > N_2$, observe that:

$$\begin{aligned} \sum_{j=0}^{N-1} \|A^j\| \|b(k-1-j) - b^*\| &< \sum_{j=0}^{N-1} \|A^j\| \frac{(1-\alpha)\epsilon}{6M} \\ &< \frac{(1-\alpha)\epsilon}{6M} \sum_{j=0}^{\infty} \|A^j\| \\ &\leq \frac{\epsilon}{6} \end{aligned} \tag{32}$$

and that:

$$\begin{aligned} \sum_{j=N}^{k-1} \|A^j\| \|b(k-1-j) - b^*\| &\leq \sum_{j=N}^{k-1} \|A^j\| (\|b(k-1-j)\| + \|b^*\|) \\ &\leq 2B \sum_{j=N}^{\infty} \|A^j\| \\ &\leq 2BM \frac{\alpha^N}{1-\alpha} \\ &\leq \frac{\epsilon}{6} \end{aligned} \tag{33}$$

We can now conclude that for $k > N_2$, we have:

$$\begin{aligned} \sum_{j=0}^{k-1} \|A^j\| \|b(k-1-j) - b^*\| &= \sum_{j=0}^{N-1} \|A^j\| \|b(k-1-j) - b^*\| + \sum_{j=N}^{k-1} \|A^j\| \|b(k-1-j) - b^*\| \\ &\leq \frac{\epsilon}{6} + \frac{\epsilon}{6} \\ &= \frac{\epsilon}{3} \end{aligned} \tag{34}$$

Finally, for the third term, once again since we have $\alpha < 1$, we can choose $N_3$ such that $\alpha^{N_3} < \frac{(1-\alpha)\epsilon}{3BM}$ such that for $k > N_3$, we have:

$$\begin{aligned} \sum_{r=k}^{\infty} \|A^r\| \|b^*\| &\leq B \sum_{r=N_3}^{\infty} \|A^r\| \\ &\leq B \frac{M\alpha^{N_3}}{1-\alpha} \\ &< \frac{\epsilon}{3} \end{aligned} \tag{35}$$

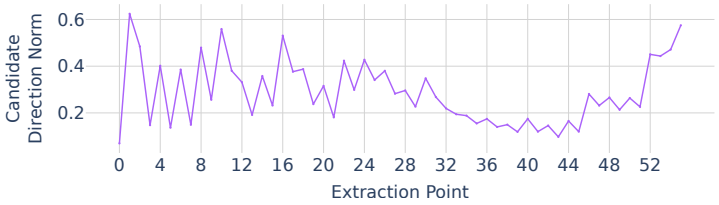

Figure 4: The norm of $\boldsymbol{r}(k)$ computed sequentially as in Equation 5 through Llama3.2-3B-Instruct

Thus, by considering $N' = \max(N_1, N_2, N_3)$, we can observe that for $k > N'$, we have:

$$\begin{aligned} \|y(k) - y^*\| &\leq \|A^k\|\|y(0)\| + \sum_{j=0}^{k-1} \|A^j\|\|(b(k-1-j) - b^*)\| + \sum_{r=k}^{\infty} \|A^r\|\|b^*\| \\ &< \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} \\ &= \epsilon \end{aligned} \tag{36}$$

completing the proof as desired. □

*Remark* D.3. If the hypotheses in Theorem D.2 hold, then the convergence established also implies that $\boldsymbol{x}(k, n)$ converges to $\boldsymbol{x}^*_{tg}(n)$.

Since the layer functions are omitted, this analysis characterizes the underlying momentum recursion rather than the full steering dynamics used in practice. Thus, whether these dynamics track the desired steering target is a separate question that is not addressed here. Nevertheless, for the momentum recursion, the analysis above provides explicit conditions on $\beta$ and $\gamma$ under which it is stable, and describes its limiting behavior.

## E Steered Responses with Momentum Steering

In this section, we provide sample generations from Gemma2-9B-Instruct on one of the prompts from the test set used in the jailbreaking experiment in Section 4.1. We showcase the responses under different settings: No Steering, regular Angular Steering without Momentum Steering and Angular Steering with Momentum Steering, and we compile them in Table 9.

In the case of Angular Steering without Momentum Steering, we note that the responses generated were unable to bypass the model's safety mechanism regardless of the angles chosen. As such, we reported the response of the angle yielding the highest attack success rate across all prompts in the test set, as recorded in Table 1.

For Angular Steering with Momentum Steering, not only can we find an angle that bypasses the safety mechanism, we can also observe different levels of steering when steering to different angles, as observed in [56]. With respect to the jailbreaking task, we follow the classification labels used to describe the different types of responses as proposed in [56]: refuse, indirect, direct and redirect, and label the responses accordingly. The responses, along with the associated label and angle it was steered to, can be observed in Table 9.

## F Steering Vector Norm of Pretrained Models

In addition to the plot of the steering vector norms $\|r(k)\|_2$ from the randomly initialized model in Figure 2, we also extend our analysis to consider pre-trained models as well. In particular, we compute the norms of the steering vectors across layers obtained via sequential steering on both Llama3.2-3B-Instruct and Llama3.1-8B-Instruct, and plot them in Figures 4 and 5 respectively. Similar to Appendix A, we note that we are following the approach from [56] in extracting the activations required for computing the steering vectors.

## G Additional Analysis on Steering Vector Alignment

Since Momentum Steering accumulates the difference-in-means steering vectors $\boldsymbol{r}(k)$ across the extraction points, we examine how the individual $\boldsymbol{r}(k)$ are aligned with each other. Following [56],

Table 9: Sample generations from Gemma2-9B-Instruct using Angular Steering with and without Momentum Steering on a prompt from the Jailbreaking Task in Section 4.1. It shows a scenario where regular Angular Steering fails to jailbreak the model but succeeds when complemented with Momentum Steering. The Best Performing Angle here indicates the angle that yields the highest attack success rate recorded in Table 1. We omit some content from the response for brevity.

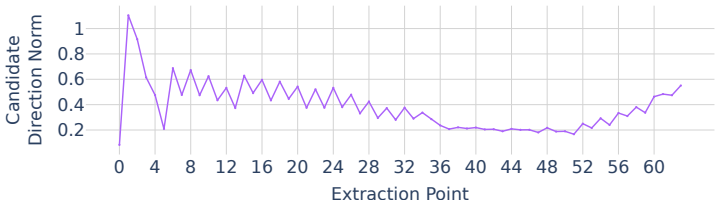

Figure 5: The norm of $\boldsymbol{r}(k)$ computed sequentially as in Equation 5 through Llama3.1-8B-Instruct

Table 10: Mean cosine similarity between $\boldsymbol{r}(k)$ and all other difference-in-means across extraction points on Llama3.2-3B-Instruct.

| $k$ | 5 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 |
|---|---|---|---|---|---|---|---|---|---|---|
| Mean Cosine Similarity | 0.126 | 0.202 | 0.250 | 0.271 | 0.317 | 0.369 | 0.412 | 0.413 | 0.393 | 0.354 |

Table 11: Performance of ActAdd with and without Momentum Steering. The extraction point denotes the layer at which the intervention is applied (layer indices start from 0). $\gamma$ denotes the intervention strength. All steering vectors are normalized to unit norm prior to inference. The momentum coefficient is denoted by $\beta$, with $\beta = 0$ corresponding to standard difference-in-means.

| Method | ASR ↑ | Extraction Point | $\gamma$ | $\beta$ |
|---|---|---|---|---|
| **Qwen2.5-3B-Instruct** | | | | |
| ActAdd (Baseline) | 49.04 | Layer 19, Input LayerNorm | 60 | 0 |
| ActAdd + Mom. | **65.38** | Layer 18, Post-Attention LayerNorm | 42.5 | 0.99 |
| **Llama3.2-3B-Instruct** | | | | |
| ActAdd (Baseline) | 60.58 | Layer 16, Input LayerNorm | 20 | 0 |
| ActAdd + Mom. | **62.50** | Layer 16, Input LayerNorm | 22.5 | 0.5 |

for each $\boldsymbol{r}(k)$ computed non-sequentially, we compute the mean cosine similarity with all other difference-in-means across extraction points on Llama3.2-3B-Instruct. We report the scores for select values of $k$ in Table 10, and we can observe that the mean cosine similarity remains consistently positive. This suggests that the difference-in-means computed across various extraction points exhibit non-trivial geometric alignment.

## H Additional Results on Activation Addition

Beyond using only Angular Steering for the jailbreaking task, we also extend our experiments to consider ActAdd. We keep the experimental settings similar to Section 4.1, but the main difference between the two settings is the method of intervention during inference, where we use ActAdd for this experiment while Section 4.1 uses Angular Steering. Furthermore, for ActAdd, the intervention is only performed in one location throughout the model. The location, along with strength of intervention, $\gamma$, are tunable hyperparameters [53, 43, 3].

We test our method on Qwen2.5-3B-Instruct and Llama3.2-3B-Instruct, and the baseline for this experiment is regular ActAdd, where the steering vector for any layer is computed using regular difference-in-means without momentum ($\beta = 0$). The results, along with the corresponding tuned hyperparameters, are compiled in Table 11, and we can observe that performing ActAdd with the steering vectors computed via Momentum Steering does improve the steering effect, as evidenced by the increased attack success rate demonstrated in both models.

## I Additional Results with Top-K Sampling

In this appendix, we extend our jailbreaking experiments to evaluate Top-K sampling during inference. In the main experiments (Section 4.1), responses were generated using greedy decoding. Here, we instead perform inference using Top-K sampling with $K = 10$ and $K = 40$, while keeping all other experimental settings identical to those described in Section 4.1.

We evaluate both Momentum Steering and Adam Steering on Gemma2-9B-Instruct and Gemma2-27B-Instruct under each choice of $K$. For every configuration, we run the experiment 10 times. The mean and standard deviation of the attack success rate (ASR) across runs are reported in Table 12.

The results show that although the ASR standard deviation is not negligible for either value of $K$, the mean ASR remains substantially higher than that obtained without Momentum or Adam Steering. This indicates that even under non-greedy decoding, momentum-based and Adam-based steering continue to yield stronger steering effects.

## J Additional Results on Inducing Refusal

In Section 4.1, the jailbreaking task aims to override the LLM's default refusal behavior. Here, we instead consider the opposite direction, steering a set of harmless prompts, which would normally

Table 12: Performance of all configurations of our method on the jailbreaking task (Section 4.1) using Top-$K$ sampling ($K = 10, 40$) for Gemma2-9B-Instruct and Gemma2-27B-Instruct. Results are averaged over 10 runs; we report mean and standard deviation of ASR.

Table 13: Performance of non-sequential Momentum Steering against the baseline in inducing refusal on Llama3.2-3B-Instruct and Qwen2.5-14B-Instruct. Higher is better. The best refusal rate is bolded.

| Method | Refusal Rate ↑ |
|---|---|
| **Llama3.2-3B-Instruct** | |
| AS (Baseline) | 20.19 |
| AS + Mom. | **55.77** |
| **Qwen2.5-14B-Instruct** | |
| AS (Baseline) | 2.88 |
| AS + Mom. | **38.46** |

have been answered by the LLM, towards inducing the LLM's refusal mechanism. We keep the experimental settings similar to Section 4.1, but we now evaluate on a new set of 104 harmless prompts from the ALPACA [48] dataset, and use substring matching, as in [56], to determine whether a response is a refusal.

We test non-sequential Momentum Steering on Llama3.2-3B-Instruct and Qwen2.5-14B-Instruct, and the baseline for this experiment is Angular Steering with regular difference-in-means. The results are compiled in Table 13, and they show that, in both models, Momentum Steering improves upon the baseline, even when steering in this opposite direction.

Table 14: Wall-clock time required to compute steering vectors with Momentum Steering, under sequential and non-sequential settings. Non-sequential steering serves as the baseline for comparison.

| Method | Seq. | Wall-clock Time (s) |
|---|---|---|
| **Qwen2.5-7B-Instruct** | | |

| Mom. (AA) | ✓ | 6.62 | 650.8 | 7775.5 | 8426.3 |
| **Qwen2.5-32B-Instruct** | | | | | |
| Mom. | | 22.43 | 192.0 | 2304.0 | 2496.0 |
| Mom. (AA) | ✓ | 22.38 | 192.4 | 2323.3 | 2515.7 |

Figure 6: Performance of Momentum-AcT and Mean-AcT for concept Cyberpunk, measured by zero-shot classification score (left) and CLIPScore (right). Both methods exhibit a similar increasing trend in zero-shot classification score. However, the gap between them in CLIPScore widens with increasing steering strength, indicating that for Mean-AcT, increased style induction comes at higher cost of semantic alignment.

Figure 7: Performance of Momentum-AcT and Mean-AcT for concept Sketch, measured by zero-shot classification score (left) and CLIPScore (right). Both methods achieve high consistency in style induction ($\geq 0.95$); however, Momentum-AcT maintains a tighter, near-ceiling performance curve (approaching 0.27) while Mean-AcT exhibits greater degradation as conditioning strength increases.

## K Additional Wall-Clock and Throughput Analysis

In this section, we provide a wall-clock and throughput analysis of Momentum Steering under the setting described in Section 4.1. We aim to demonstrate that the additional precomputation cost of sequential steering remains practical even as model size increases, and that the inference cost does not vary between sequential and non-sequential settings, as noted in Remark 3.6.

We perform this analysis on Qwen2.5-7B-Instruct and Qwen2.5-32B-Instruct, and we measure the wall-clock time required to generate steering vectors with HuggingFace Transformers on a single NVIDIA H100 GPU under sequential and non-sequential settings, and report the results in Table 14. We also measure inference throughput using the resulting precomputed steering vectors and report these statistics in Table 15.

Figure 8: Images generated with FLUX.1.Schnell under Momentum-AcT interventions to induce the concept Cyberpunk. **First Row:** *"Orange fire hydrant on the sidewalk in a commercial area"* **Second Row:** *"A large tower that has a big clock at top."* **Third Row:** *"Lady bent over with red polka dot umbrella inside a brick building."* **Fourth Row:** *"Skate boarder hang time with young man appearing to streak though the air."* **Fifth Row:** *"A couple of computers that are sitting on a desk."* **Sixth Row:** *"A cat sitting on a toilet in a bathroom."*

Table 14 demonstrates that, although sequential steering incurs additional precomputation cost, it remains practical taking approximately 22 minutes even for Qwen2.5-32B-Instruct and less for smaller models. Table 15 further shows that the inference throughputs are nearly identical in the two settings, verifying that the sequential variant does not incur any additional computational overhead during inference.

## L Additional Results on Style Control

We study activation steering in diffusion models using the denoising transformer of FLUX.1.Schnell [23], built on T5-XXL encoders [42]. We intervene on normalization layers following [44] using

Figure 9: Images generated with FLUX.1.Schnell under Momentum-AcT interventions to induce the concept Sketch. **First Row:** *"Orange fire hydrant on the sidewalk in a commercial area"* **Second Row:** *"A large tower that has a big clock at top."* **Third Row:** *"Lady bent over with red polka dot umbrella inside a brick building."* **Fourth Row:** *"Skate boarder hang time with young man appearing to streak though the air."* **Fifth Row:** *"A couple of computers that are sitting on a desk."* **Sixth Row:** *"A cat sitting on a toilet in a bathroom."*

Momentum-AcT, and report our results in Figures 6 and 7. We test our method on inducing two styles, Cyberpunk and Sketch. The zero-shot score, evaluated with a CLIP-based classifier, measures the extent to which the style or concept is expressed in the image, while content preservation is measured via CLIPScore. Qualitatively, increasing intervention strength yields smooth, coherent style transitions while preserving scene structure, with strong yet faithful stylization at moderate strengths, as seen in Figures 8 and 9. Quantitatively, both Mom-AcT and Mean-AcT exhibit similar zero-shot scores, while Mom-AcT degrades more slowly compared to Mean-AcT, as shown by the slower decrease in CLIPScore, demonstrating that our method preserves semantic grounding even under strong stylistic perturbation.

## M Broader Societal Impacts

Our work introduces Momentum Steering, which extends activation steering with momentum-based updates for constructing steering directions. On the positive side, Momentum Steering may improve model controllability and safety, as demonstrated by our toxicity mitigation experiments, while remaining lightweight and modular. However, similar to prior work on activation steering, our method can also be misused to circumvent safety alignment mechanisms and induce harmful behaviors in aligned models, as illustrated by our jailbreaking experiments. We therefore believe that advances in activation steering should be accompanied by corresponding research into robustness and defenses against adversarial interventions. Overall, we hope this work contributes to a better understanding of controllability and representation manipulation in large language models.

## NeurIPS Paper Checklist

The checklist is designed to encourage best practices for responsible machine learning research, addressing issues of reproducibility, transparency, research ethics, and societal impact. Do not remove the checklist: **The papers not including the checklist will be desk rejected.** The checklist should follow the references and follow the (optional) supplemental material. The checklist does NOT count towards the page limit.

Please read the checklist guidelines carefully for information on how to answer these questions. For each question in the checklist:

- You should answer [Yes], [No], or [N/A].
- [N/A] means either that the question is Not Applicable for that particular paper or the relevant information is Not Available.
- Please provide a short (1–2 sentence) justification right after your answer (even for [N/A]).

**The checklist answers are an integral part of your paper submission.** They are visible to the reviewers, area chairs, senior area chairs, and ethics reviewers. You will also be asked to include it (after eventual revisions) with the final version of your paper, and its final version will be published with the paper.

The reviewers of your paper will be asked to use the checklist as one of the factors in their evaluation. While [Yes] is generally preferable to [No], it is perfectly acceptable to answer [No] provided a proper justification is given (e.g., error bars are not reported because it would be too computationally expensive" or "we were unable to find the license for the dataset we used"). In general, answering [No] or [N/A] is not grounds for rejection. While the questions are phrased in a binary way, we acknowledge that the true answer is often more nuanced, so please just use your best judgment and write a justification to elaborate. All supporting evidence can appear either in the main paper or the supplemental material, provided in appendix. If you answer [Yes] to a question, in the justification please point to the section(s) where related material for the question can be found.

1. **Claims**

   Question: Do the main claims made in the abstract and introduction accurately reflect the paper's contributions and scope?

   Answer: [Yes]

   Justification: The main claims made in the abstract and introduction do accurately reflect the paper's contributions and scope. This is supported by the framework and our methods introduced in Section 3 and the empirical results in Section 4.

   Guidelines:

   - The answer [N/A] means that the abstract and introduction do not include the claims made in the paper.
   - The abstract and/or introduction should clearly state the claims made, including the contributions made in the paper and important assumptions and limitations. A [No] or [N/A] answer to this question will not be perceived well by the reviewers.
   - The claims made should match theoretical and experimental results, and reflect how much the results can be expected to generalize to other settings.
   - It is fine to include aspirational goals as motivation as long as it is clear that these goals are not attained by the paper.

2. **Limitations**

   Question: Does the paper discuss the limitations of the work performed by the authors?

   Answer: [Yes]

   Justification: We discuss the limitations of our work in Section 6, namely the sensitivity to $\beta$ and the inconsistent gains across model families. The scope and limitations of our theoretical results are also stated in Remark 3.2 and Appendix D.

   Guidelines:

- The answer [N/A] means that the paper has no limitation while the answer [No] means that the paper has limitations, but those are not discussed in the paper.
- The authors are encouraged to create a separate "Limitations" section in their paper.
- The paper should point out any strong assumptions and how robust the results are to violations of these assumptions (e.g., independence assumptions, noiseless settings, model well-specification, asymptotic approximations only holding locally). The authors should reflect on how these assumptions might be violated in practice and what the implications would be.
- The authors should reflect on the scope of the claims made, e.g., if the approach was only tested on a few datasets or with a few runs. In general, empirical results often depend on implicit assumptions, which should be articulated.
- The authors should reflect on the factors that influence the performance of the approach. For example, a facial recognition algorithm may perform poorly when image resolution is low or images are taken in low lighting. Or a speech-to-text system might not be used reliably to provide closed captions for online lectures because it fails to handle technical jargon.
- The authors should discuss the computational efficiency of the proposed algorithms and how they scale with dataset size.
- If applicable, the authors should discuss possible limitations of their approach to address problems of privacy and fairness.
- While the authors might fear that complete honesty about limitations might be used by reviewers as grounds for rejection, a worse outcome might be that reviewers discover limitations that aren't acknowledged in the paper. The authors should use their best judgment and recognize that individual actions in favor of transparency play an important role in developing norms that preserve the integrity of the community. Reviewers will be specifically instructed to not penalize honesty concerning limitations.

3. **Theory assumptions and proofs**

   Question: For each theoretical result, does the paper provide the full set of assumptions and a complete (and correct) proof?

   Answer: [Yes]

   Justification: We list the full set of assumptions used in Section 3 and in Appendix D.

   Guidelines:

   - The answer [N/A] means that the paper does not include theoretical results.
   - All the theorems, formulas, and proofs in the paper should be numbered and cross-referenced.
   - All assumptions should be clearly stated or referenced in the statement of any theorems.
   - The proofs can either appear in the main paper or the supplemental material, but if they appear in the supplemental material, the authors are encouraged to provide a short proof sketch to provide intuition.
   - Inversely, any informal proof provided in the core of the paper should be complemented by formal proofs provided in appendix or supplemental material.
   - Theorems and Lemmas that the proof relies upon should be properly referenced.

4. **Experimental result reproducibility**

   Question: Does the paper fully disclose all the information needed to reproduce the main experimental results of the paper to the extent that it affects the main claims and/or conclusions of the paper (regardless of whether the code and data are provided or not)?

   Answer: [Yes]

   Justification: We believe the experimental setups described in Section 4 are sufficiently detailed to reproduce the main results. Additionally, we have provided the source code in our supplementary materials.

   Guidelines:

   - The answer [N/A] means that the paper does not include experiments.

- If the paper includes experiments, a [No] answer to this question will not be perceived well by the reviewers: Making the paper reproducible is important, regardless of whether the code and data are provided or not.
- If the contribution is a dataset and/or model, the authors should describe the steps taken to make their results reproducible or verifiable.
- Depending on the contribution, reproducibility can be accomplished in various ways. For example, if the contribution is a novel architecture, describing the architecture fully might suffice, or if the contribution is a specific model and empirical evaluation, it may be necessary to either make it possible for others to replicate the model with the same dataset, or provide access to the model. In general. releasing code and data is often one good way to accomplish this, but reproducibility can also be provided via detailed instructions for how to replicate the results, access to a hosted model (e.g., in the case of a large language model), releasing of a model checkpoint, or other means that are appropriate to the research performed.
- While NeurIPS does not require releasing code, the conference does require all submissions to provide some reasonable avenue for reproducibility, which may depend on the nature of the contribution. For example
  (a) If the contribution is primarily a new algorithm, the paper should make it clear how to reproduce that algorithm.
  (b) If the contribution is primarily a new model architecture, the paper should describe the architecture clearly and fully.
  (c) If the contribution is a new model (e.g., a large language model), then there should either be a way to access this model for reproducing the results or a way to reproduce the model (e.g., with an open-source dataset or instructions for how to construct the dataset).
  (d) We recognize that reproducibility may be tricky in some cases, in which case authors are welcome to describe the particular way they provide for reproducibility. In the case of closed-source models, it may be that access to the model is limited in some way (e.g., to registered users), but it should be possible for other researchers to have some path to reproducing or verifying the results.

5. **Open access to data and code**

   Question: Does the paper provide open access to the data and code, with sufficient instructions to faithfully reproduce the main experimental results, as described in supplemental material?

   Answer: [Yes]

   Justification: We have included the code in our supplementary, and instructions on how to reproduce the experimental results. In addition, the datasets and models used are publicly available.

   Guidelines:

   - The answer [N/A] means that paper does not include experiments requiring code.
   - Please see the NeurIPS code and data submission guidelines (https://neurips.cc/public/guides/CodeSubmissionPolicy) for more details.
   - While we encourage the release of code and data, we understand that this might not be possible, so [No] is an acceptable answer. Papers cannot be rejected simply for not including code, unless this is central to the contribution (e.g., for a new open-source benchmark).
   - The instructions should contain the exact command and environment needed to run to reproduce the results. See the NeurIPS code and data submission guidelines (https://neurips.cc/public/guides/CodeSubmissionPolicy) for more details.
   - The authors should provide instructions on data access and preparation, including how to access the raw data, preprocessed data, intermediate data, and generated data, etc.
   - The authors should provide scripts to reproduce all experimental results for the new proposed method and baselines. If only a subset of experiments are reproducible, they should state which ones are omitted from the script and why.
   - At submission time, to preserve anonymity, the authors should release anonymized versions (if applicable).

- Providing as much information as possible in supplemental material (appended to the paper) is recommended, but including URLs to data and code is permitted.

6. **Experimental setting/details**

   Question: Does the paper specify all the training and test details (e.g., data splits, hyperparameters, how they were chosen, type of optimizer) necessary to understand the results?

   Answer: [Yes]

   Justification: We have specified experimental setup, inclusive of data splits and chosen hyperparameters, in our experiment section, Section 4.

   Guidelines:

   - The answer [N/A] means that the paper does not include experiments.
   - The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them.
   - The full details can be provided either with the code, in appendix, or as supplemental material.

7. **Experiment statistical significance**

   Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?

   Answer: [Yes]

   Justification: We report error bars of our results in Table 4, under Section 4.3.

   Guidelines:

   - The answer [N/A] means that the paper does not include experiments.
   - The authors should answer [Yes] if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper.
   - The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions).
   - The method for calculating the error bars should be explained (closed form formula, call to a library function, bootstrap, etc.)
   - The assumptions made should be given (e.g., Normally distributed errors).
   - It should be clear whether the error bar is the standard deviation or the standard error of the mean.
   - It is OK to report 1-sigma error bars, but one should state it. The authors should preferably report a 2-sigma error bar than state that they have a 96% CI, if the hypothesis of Normality of errors is not verified.
   - For asymmetric distributions, the authors should be careful not to show in tables or figures symmetric error bars that would yield results that are out of range (e.g., negative error rates).
   - If error bars are reported in tables or plots, the authors should explain in the text how they were calculated and reference the corresponding figures or tables in the text.

8. **Experiments compute resources**

   Question: For each experiment, does the paper provide sufficient information on the computer resources (type of compute workers, memory, time of execution) needed to reproduce the experiments?

   Answer: [Yes]

   Justification: We listed the computing resources used for all our experiments in the beginning of Section 4.

   Guidelines:

   - The answer [N/A] means that the paper does not include experiments.
   - The paper should indicate the type of compute workers CPU or GPU, internal cluster, or cloud provider, including relevant memory and storage.

- The paper should provide the amount of compute required for each of the individual experimental runs as well as estimate the total compute.
- The paper should disclose whether the full research project required more compute than the experiments reported in the paper (e.g., preliminary or failed experiments that didn't make it into the paper).

9. **Code of ethics**

   Question: Does the research conducted in the paper conform, in every respect, with the NeurIPS Code of Ethics https://neurips.cc/public/EthicsGuidelines?

   Answer: [Yes]

   Justification: The research conducted in the paper conforms, in every respect, with the NeurIPS Code of Ethics.

   Guidelines:

   - The answer [N/A] means that the authors have not reviewed the NeurIPS Code of Ethics.
   - If the authors answer [No], they should explain the special circumstances that require a deviation from the Code of Ethics.
   - The authors should make sure to preserve anonymity (e.g., if there is a special consideration due to laws or regulations in their jurisdiction).

10. **Broader impacts**

    Question: Does the paper discuss both potential positive societal impacts and negative societal impacts of the work performed?

    Answer: [Yes]

    Justification: We have discussed the broader societal impacts of our work in Appendix M.

    Guidelines:

    - The answer [N/A] means that there is no societal impact of the work performed.
    - If the authors answer [N/A] or [No], they should explain why their work has no societal impact or why the paper does not address societal impact.
    - Examples of negative societal impacts include potential malicious or unintended uses (e.g., disinformation, generating fake profiles, surveillance), fairness considerations (e.g., deployment of technologies that could make decisions that unfairly impact specific groups), privacy considerations, and security considerations.
    - The conference expects that many papers will be foundational research and not tied to particular applications, let alone deployments. However, if there is a direct path to any negative applications, the authors should point it out. For example, it is legitimate to point out that an improvement in the quality of generative models could be used to generate Deepfakes for disinformation. On the other hand, it is not needed to point out that a generic algorithm for optimizing neural networks could enable people to train models that generate Deepfakes faster.
    - The authors should consider possible harms that could arise when the technology is being used as intended and functioning correctly, harms that could arise when the technology is being used as intended but gives incorrect results, and harms following from (intentional or unintentional) misuse of the technology.
    - If there are negative societal impacts, the authors could also discuss possible mitigation strategies (e.g., gated release of models, providing defenses in addition to attacks, mechanisms for monitoring misuse, mechanisms to monitor how a system learns from feedback over time, improving the efficiency and accessibility of ML).

11. **Safeguards**

    Question: Does the paper describe safeguards that have been put in place for responsible release of data or models that have a high risk for misuse (e.g., pre-trained language models, image generators, or scraped datasets)?

    Answer: [Yes]

Justification: Our experiments rely entirely on established public benchmarks which are already openly available under their respective licenses, and we do not release any new harmful or scraped data.

Guidelines:

- The answer [N/A] means that the paper poses no such risks.
- Released models that have a high risk for misuse or dual-use should be released with necessary safeguards to allow for controlled use of the model, for example by requiring that users adhere to usage guidelines or restrictions to access the model or implementing safety filters.
- Datasets that have been scraped from the Internet could pose safety risks. The authors should describe how they avoided releasing unsafe images.
- We recognize that providing effective safeguards is challenging, and many papers do not require this, but we encourage authors to take this into account and make a best faith effort.

12. **Licenses for existing assets**

Question: Are the creators or original owners of assets (e.g., code, data, models), used in the paper, properly credited and are the license and terms of use explicitly mentioned and properly respected?

Answer: [Yes]

Justification: All datasets, models, and codebases used in this work are properly credited via citations to their original authors.

Guidelines:

- The answer [N/A] means that the paper does not use existing assets.
- The authors should cite the original paper that produced the code package or dataset.
- The authors should state which version of the asset is used and, if possible, include a URL.
- The name of the license (e.g., CC-BY 4.0) should be included for each asset.
- For scraped data from a particular source (e.g., website), the copyright and terms of service of that source should be provided.
- If assets are released, the license, copyright information, and terms of use in the package should be provided. For popular datasets, paperswithcode.com/datasets has curated licenses for some datasets. Their licensing guide can help determine the license of a dataset.
- For existing datasets that are re-packaged, both the original license and the license of the derived asset (if it has changed) should be provided.
- If this information is not available online, the authors are encouraged to reach out to the asset's creators.

13. **New assets**

Question: Are new assets introduced in the paper well documented and is the documentation provided alongside the assets?

Answer: [Yes]

Justification: The source code used for this paper is based on existing sources (which have been credited properly). We also provide a README file to run the code.

Guidelines:

- The answer [N/A] means that the paper does not release new assets.
- Researchers should communicate the details of the dataset/code/model as part of their submissions via structured templates. This includes details about training, license, limitations, etc.
- The paper should discuss whether and how consent was obtained from people whose asset is used.
- At submission time, remember to anonymize your assets (if applicable). You can either create an anonymized URL or include an anonymized zip file.

14. **Crowdsourcing and research with human subjects**

    Question: For crowdsourcing experiments and research with human subjects, does the paper include the full text of instructions given to participants and screenshots, if applicable, as well as details about compensation (if any)?

    Answer: [N/A]

    Justification: This work does not contain any crowdsourcing experiments and research with human subjects.

    Guidelines:

    - The answer [N/A] means that the paper does not involve crowdsourcing nor research with human subjects.
    - Including this information in the supplemental material is fine, but if the main contribution of the paper involves human subjects, then as much detail as possible should be included in the main paper.
    - According to the NeurIPS Code of Ethics, workers involved in data collection, curation, or other labor should be paid at least the minimum wage in the country of the data collector.

15. **Institutional review board (IRB) approvals or equivalent for research with human subjects**

    Question: Does the paper describe potential risks incurred by study participants, whether such risks were disclosed to the subjects, and whether Institutional Review Board (IRB) approvals (or an equivalent approval/review based on the requirements of your country or institution) were obtained?

    Answer: [N/A]

    Justification: This work does not contain any crowdsourcing experiments and research with human subjects.

    Guidelines:

    - The answer [N/A] means that the paper does not involve crowdsourcing nor research with human subjects.
    - Depending on the country in which research is conducted, IRB approval (or equivalent) may be required for any human subjects research. If you obtained IRB approval, you should clearly state this in the paper.
    - We recognize that the procedures for this may vary significantly between institutions and locations, and we expect authors to adhere to the NeurIPS Code of Ethics and the guidelines for their institution.
    - For initial submissions, do not include any information that would break anonymity (if applicable), such as the institution conducting the review.

16. **Declaration of LLM usage**

    Question: Does the paper describe the usage of LLMs if it is an important, original, or non-standard component of the core methods in this research? Note that if the LLM is used only for writing, editing, or formatting purposes and does *not* impact the core methodology, scientific rigor, or originality of the research, declaration is not required.

    Answer: [N/A]

    Justification: The core methodology, scientific rigor, or originality of the research do not rely on LLMs in any important, original, or non-standard way.

    Guidelines:

    - The answer [N/A] means that the core method development in this research does not involve LLMs as any important, original, or non-standard components.
    - Please refer to our LLM policy in the NeurIPS handbook for what should or should not be described.
