RAHL: RECURSIVE SELF-IMPROVEMENT THROUGH REPAIRABILITY-AWARE HINDSIGHT LEARNING

Anonymous authors
Paper under double-blind review

ABSTRACT

Language agents can fail their assigned tasks while achieving other goals along the way. Hindsight relabeling can recover these successes, but changing the goal alone may leave recorded plans inconsistent with the new task. Goals achieved by the same trajectory can differ in how much plan revision they require. We introduce Repairability-Aware Hindsight Learning (RAHL), which selects verified goals according to the cost of repairing their associated plans. The acting policy revises plans in execution order, conditioning each edit on the previously repaired history. A policy-generated mask restricts edits to spans classified as goal-specific intentions, while recorded actions and observations remain unchanged. Among candidates that satisfy the editing constraints, RAHL favors those requiring fewer token changes. Each replay-verified demonstration is paired with new rollouts from the same initial state for training alongside original tasks. The updated policy then acts, proposes goals, and repairs demonstrations in the next round, forming a recursive actor–relabeler loop. Experiments show higher GRPO task success on ALFWorld, WebShop, and ScienceWorld at matched training rounds, with gains depending on the optimizer. On identical WebShop histories, the trained relabeler yields more replay-verified demonstrations, while demonstration yield per model call remains similar.

1 INTRODUCTION

An unsuccessful attempt at a task can still contain behavior that a language agent can learn from. The agent may complete a subgoal, satisfy a different request, or achieve an unrelated goal during exploration. For example, it might pick up an object but fail to place it, buy a red mug when asked for a blue one, or clean an unrelated object.

Reinforcement learning on the assigned task evaluates these interactions against goal A. In Group Relative Policy Optimization (GRPO), identical rewards within a rollout group yield zero group-relative reward advantages, even when the interactions achieve another goal B (Figure 1) (Shao et al., 2024).

Hindsight learning recovers supervision by assigning achieved goals to recorded interactions (Andrychowicz et al., 2017; Ding, 2026). HSL learns from achieved-goal demonstrations; LfH relabels and re-scores existing rollout groups (Li et al., 2026b; Xu et al., 2026). When an agent writes plans before acting, its actions may satisfy a new goal while those plans still pursue the original task. A single trajectory can achieve several goals, each requiring different revisions to these plans.

We therefore select achieved goals by the cost of repairing plans while keeping recorded actions and observations fixed. In Figure 1, "The mug is red" stays unchanged, while "Buy a blue mug" becomes "Buy this red mug." Among candidates that satisfy the editing constraints, we favor fewer token changes to the policy's recorded plans.

We introduce *Repairability-Aware Hindsight Learning* (RAHL), which uses the acting policy to construct its own demonstrations (Figure 2). The policy proposes goals from low-reward interactions, and an environment verifier identifies when each goal was first achieved. Plan repair then

Reviewers: please read the Reviewer Guidelines (iclr.cc/Conferences/2027/ReviewerGuidelines) and the AI Policy for Reviewers (iclr.cc/Conferences/2027/AIPolicyForReviewers). If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.

Figure 1: An agent fails task A (buy a blue mug) but achieves B (buy a red mug). Left: equal rewards for A within a rollout group give GRPO zero group-relative reward advantages. Right: RAHL selects B by plan-repair cost, keeps factual text and recorded execution, and pairs the repaired demonstration (seed) with new B rollouts. Bottom: the updated shared policy constructs supervision for the next round.

proceeds in execution order: each edit uses the already revised history, changes goal-dependent text, and preserves the recorded actions and observations. An edit mask permits changes only to text classified as goal-specific intentions, leaving all other text unchanged.

Each retained demonstration reuses an action sequence produced by the policy itself, rather than a new solution supplied by an oracle. It provides a verified success even when the policy cannot reproduce that outcome reliably under the relabeled instruction. RAHL pairs it with new rollouts from the same initial state to learn from both the recorded success and the policy's current attempts. Joint updates on original and relabeled tasks change both future behavior and the shared policy that proposes goals and repairs demonstrations for the next round.

We evaluate RAHL on ALFWorld, WebShop, and ScienceWorld, using action-only policies for ALFWorld and short-plan policies for the other environments. At matched training rounds, GRPO + RAHL raises ALFWorld unseen success from 84.33% to 91.79% and WebShop success from 68.20% to 74.20%. ScienceWorld gains are smaller, and WebShop comparisons with GSPO and GiGPO show that the benefit depends on the optimizer. On the same 64 recorded WebShop histories, the trained relabeler produces verified demonstrations from 36 sources, compared with 32 for the initial model.

We make three contributions.

- We introduce repairability-aware goal selection, which ranks achieved goals by the cost of plan edits that preserve recorded actions and observations.
- We develop chronological span editing with a policy-generated mask that permits changes only to text classified as goal-specific intentions.
- We formulate a recursive actor–relabeler loop in which policy updates also change the model that proposes goals and repairs training demonstrations.

2 Related Work

Goal relabeling. Goal relabeling assigns achieved outcomes to alternative training objectives, with extensions to policy gradients and sampling correction (Rauber et al., 2017; Schramm et al., 2023). HER established this approach for sparse-reward control (Andrychowicz et al., 2017); HSL and AgentHER construct achieved-goal demonstrations for language agents (Li et al., 2026b; Ding, 2026). CodeIt uses prioritized hindsight replay (Butt et al., 2024); LfH relabels and re-scores existing rollout groups for joint original/hindsight learning (Xu et al., 2026). RAHL selects goals through constrained plan repair, then pairs a retained success with new rollouts under the selected goal.

Trajectory editing and successful experience. Experience reuse differs in what is revised and how retained samples enter learning. ECHO rewrites goals and trajectory steps for memory-based adaptation (Hu et al., 2025); RAHL fixes executed actions and observations while editing goal-dependent plans. Reflexion and Self-Refine use verbal feedback (Shinn et al., 2023; Madaan et al., 2023), while process supervision evaluates intermediate reasoning (Lightman et al., 2024). HAPO reuses verified successes in policy optimization (Wu et al., 2026), while adaptive rollout and response reuse address sampling efficiency (Zhang et al., 2025b). HSL masks irrelevant action losses and reweights demonstrations (Li et al., 2026b); RAHL repairs recorded plans and compares coupled learning with separate demonstration imitation.

Agent reinforcement learning. Multi-turn agent training couples environment interaction, reward, and policy optimization (Wang et al., 2025; Xi et al., 2025; Zhang et al., 2025a; Wang & Ammanabrolu, 2025). Credit assignment uses group structure (Feng et al., 2026), fine-grained rewards (Wei et al., 2025), or verifier instrumentation (Li et al., 2026a). Skill1 jointly trains skill selection, utilization, and distillation, while SkillForge develops reusable skills (Shi et al., 2026; Yang et al., 2026). RAHL constructs goal-conditioned training demonstrations from achieved behavior and learns a policy that acts without retrieving a skill library.

Self-improvement. Self-improvement methods differ in which component is updated: parameters, task-generation procedures, or reusable agent context. Self-play fine-tuning and self-generated data filtering support parameter updates (Chen et al., 2024; Jiang et al., 2025); Absolute Zero shares a model between verified task proposal and solving (Zhao et al., 2025). Recent recursive approaches evolve task and meta-skills (Wang et al., 2026), refine exploration through replayed histories (Zheng et al., 2026), or construct reusable environment memories (Zhu et al., 2026). RAHL updates a shared actor and relabeler through original-task and hindsight learning, with original tasks drawn from benchmark training sets. The updated policy proposes goals and repairs the next round of demonstrations, linking learning to supervision construction (Meng et al., 2026; Tang et al., 2026). Comparing relabelers on the same recorded histories separates changes in supervision construction from changes in the actor's collected experience.

3 METHOD

RAHL augments original-task reinforcement learning with demonstrations constructed by the current policy from its own experience. Figure 2 links three operations: verify achieved goals, repair recorded plans, and select a demonstration for auxiliary learning. Goal selection depends on verified achievement and the cost of revisions that satisfy the editing constraints.

3.1 TASKS, HISTORIES, AND THE SHARED POLICY

Let $A \sim \mathcal{D}_A$ be an original task and $\tau = (o_0, z_1, a_1, o_1, \ldots, z_T, a_T, o_T)$ its history, with public observations o_t, optional plans z_t, and executed actions a_t (Yao et al., 2023). The physical projection $\mathrm{phys}(\tau) = (o_0, a_1, o_1, \ldots, a_T, o_T)$ excludes plans and the task instruction. We evaluate the expected native task return $J_A(\theta) = \mathbb{E}_{A,\tau\sim\pi_\theta(\cdot|A)}[R_A^{\mathrm{native}}(\tau)]$. At round k, π_k is frozen during collection and constructs auxiliary goals B from trajectories with $R_A^{\mathrm{native}}(\tau) < 1$. Its parameters serve the actor and the relabeler: a goal proposer, span classifier, and plan editor; a fixed environment verifier determines achievement.

3.2 FROM ACHIEVED OUTCOMES TO AUXILIARY GOALS

The proposer reads public observations and actions and returns at most two goals in a fixed, typed goal language. Each goal receives a relation label b describing it as a subgoal, alternative, or incidental achievement relative to A; candidates with the same label form a selection group, or bucket. ALFWorld goals describe object handling and temporal relations; WebShop goals specify purchase conditions; ScienceWorld goals describe object handling and state changes. Appendix B gives the goal grammars and relation-label sources. Instructions specify reusable conditions, while separate verification records, or witnesses, identify the entities and events that satisfy them.

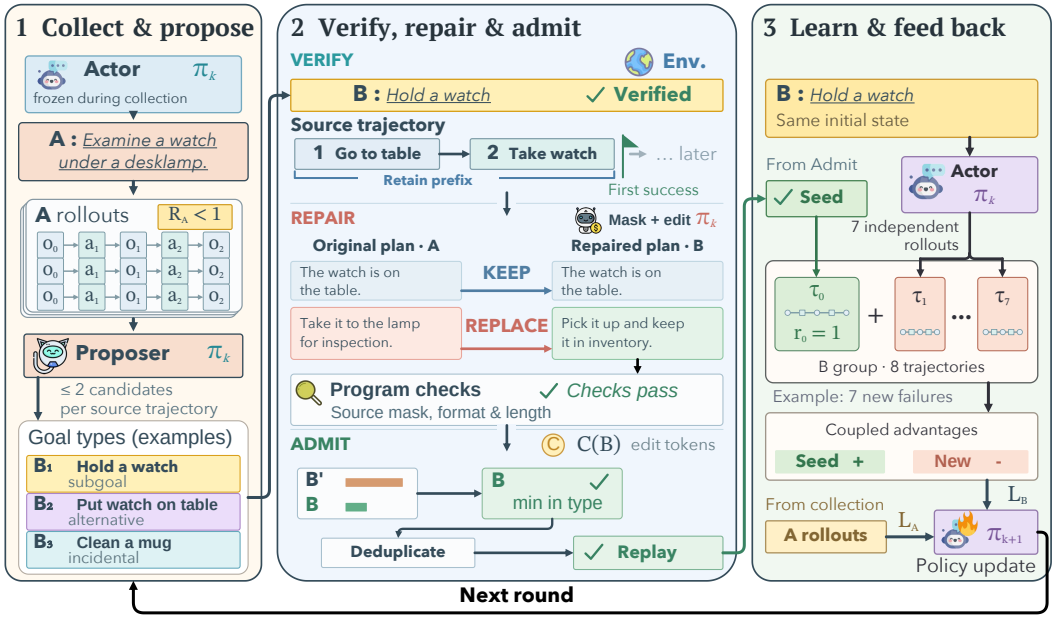

Figure 2: The RAHL construction and learning loop, with illustrative goal types across source histories. Actor, proposer, span classifier, and editor share the policy frozen during collection; a fixed environment verifier identifies achieved goals and their first successful steps. The classifier marks editable intentions, and the editor revises them using the public interaction history; action-only histories bypass repair. Selection, deduplication, and replay yield a demonstration paired with seven new rollouts from the same initial state; the updated policy acts and relabels in the next round.

A native verifier V_B checks the proposed goal against the environment history and determines its first achievement:

$$t_B = \min\{t \geq 1 : V_B(s_{0:t}) = 1\}, \qquad \tau_B^{\text{phys}} = \text{phys}(\tau)_{0:t_B}. \tag{1}$$

Here s_t denotes verifier-side state, which is excluded from the actor's public context. We reject goals that hold at reset, repeat the source instruction, lack the required public evidence, or use an invalid execution prefix. The retained prefix includes every real action and observation through t_B. Each goal that passes verification determines the recorded prefix used for subsequent plan repair.

3.3 Chronological repair of goal-dependent plans

A repaired plan must remain coherent with the history that precedes it. At step t, the editor receives B, the current observation, the original spans, their edit mask, and the B history containing all previously accepted edits. It processes plans chronologically and conditions each change on this already repaired history. The current executed action, future observations, and the first-success index t_B are excluded from the editing request.

The program partitions an existing plan into sentence or clause spans, each with a stable identifier and a hash of its original text. The policy classifies spans by function; only goal-specific intentions are editable, while factual, mixed, generic, and unknown spans are protected. For each span, the editor returns KEEP or REPLACE; replacements identify changed goal conditions, and KEEP preserves the original bytes. For example, a goal-specific intention can change while a separate factual span about the object's location remains unchanged.

The program applies only edits allowed by the mask and restores all protected spans. A revised plan must pass checks on format, source hashes, span coverage, length, and premature claims of purchase completion. The original-plan control tests the training effect of these edits (Section 4). Short-plan

policies generate and learn both plans and actions, while action-only histories retain their physical prefixes without editing.

3.4 SELECTING REPAIRABLE DEMONSTRATIONS

For source τ and relation bucket b, let $\mathcal{N}_{\tau,b}$ contain the native-valid goals. The repairable set $\mathcal{F}_{\tau,b} \subseteq \mathcal{N}_{\tau,b}$ contains candidates whose revised histories pass the editing constraints under the current policy and construction budget. RAHL samples a nonempty native-valid bucket uniformly, then chooses a repairable candidate with minimum inserted-plus-deleted token cost $C(B)$, breaking ties uniformly:

$$\mathcal{F}^*_{\tau,b} = \arg\min_{B \in \mathcal{F}_{\tau,b}} C(B), \qquad P(B \mid \tau, b) = \frac{\mathbf{1}[B \in \mathcal{F}^*_{\tau,b}]}{|\mathcal{F}^*_{\tau,b}|}. \tag{2}$$

An empty repairable set yields no B for that source, without resampling another bucket. Repair-uniform samples uniformly from $\mathcal{F}$; native-uniform samples once from $\mathcal{N}$ and discards a candidate that fails the editing constraints. For fixed nonempty $\mathcal{F} \subseteq \mathcal{N}$, native-uniform retains a candidate with probability $|\mathcal{F}|/|\mathcal{N}|$; conditional on retention, its selection is uniform over $\mathcal{F}$. Action-only histories have no plans to repair, so $\mathcal{F}_{\tau,b} = \mathcal{N}_{\tau,b}$ and selection is uniform within the sampled relation bucket. After selection, we remove duplicate reset/goal pairs and verify each retained demonstration by replay before auxiliary learning.

3.5 LEARNING FROM A DEMONSTRATION AND NEW ROLLOUTS

Each selected demonstration, called the seed, is replayed to check its actions, observations, success, and first successful step; a mismatch excludes that B group from learning. The demonstration supplies a known success, while seven new rollouts sample the current policy from the same initial state in separate environment sessions. Index the demonstration by $i = 0$ and the new rollouts by $i = 1, \ldots, 7$, with binary B-verifier rewards $r_i \in \{0, 1\}$ and $r_0 = 1$. A rewards are native success for ALFWorld, ten times native success for WebShop, and native score for ScienceWorld, each reduced by its invalid-action penalty (Appendix E). For the GRPO backend, the clipped policy loss for output token y_{iu} with history h_{iu} is (Shao et al., 2024; Schulman et al., 2017)

$$\phi_{iu}(a) = -\min\{\rho_{iu} a, \mathrm{clip}(\rho_{iu}, 1-\epsilon, 1+\epsilon)a\}, \qquad \rho_{iu} = \frac{\pi_\theta(y_{iu} \mid h_{iu})}{p^{\mathrm{old}}_{iu}}. \tag{3}$$

The frozen round policy scores both new rollouts and replayed demonstrations to obtain p^{old}_{iu}, with demonstrations scored under B. We compute advantages by subtracting the group mean reward from each reward and dividing by the sample standard deviation, floored at 10^{-6}. The coupled objective computes $\hat{a}_i$ from $[1, r_1, \ldots, r_7]$; the decoupled control computes $\tilde{a}_i$ from the seven new rewards and imitates the demonstration separately. Writing n_i for trajectory i's output-token count, $N_g = \sum_{i=0}^{7} n_i$, and $N_F = \sum_{i=1}^{7} n_i$, we use

$$L^{\mathrm{cpl}}_B = \frac{\eta \sum_u \phi_{0u}(\hat{a}_0) + \sum_{i=1}^{7} \sum_u \phi_{iu}(\hat{a}_i)}{N_g}, \tag{4}$$

$$L^{\mathrm{dec}}_B = \alpha\, \mathrm{CE}_0 + \frac{1}{N_F} \sum_{i=1}^{7} \sum_u \phi_{iu}(\tilde{a}_i), \quad \mathrm{CE}_0 = -\frac{1}{n_0} \sum_u \log \pi_\theta(y_{0u} \mid h_{0u}). \tag{5}$$

When all seven new rollouts fail, coupled advantages are $\hat{a}_0 = 7/\sqrt{8}$ and $\hat{a}_i = -1/\sqrt{8}$; decoupled rollout advantages vanish, leaving demonstration imitation. We use fixed weights $\eta = 0.5$ and $\alpha \approx 0.16535946$. When all seven new rollouts succeed, both B objectives are set to zero, including demonstration imitation. For effective replay-verified groups $\mathcal{S}$ and $M = 4$ scheduled slots, the round-level objective is

$$L(\theta) = L_A(\theta) + \frac{\lambda_B}{M} \sum_{g \in \mathcal{S}} L_{B,g}(\theta), \qquad \lambda_B = 0.25. \tag{6}$$

Here L_A averages the A-token surrogate with KL and entropy terms over all A output tokens; missing and skipped B groups contribute zero under the fixed denominator M. Training applies these weights in sequential 256-turn minibatches, with token-count rescaling; old probabilities and advantages remain fixed within the round. The updated parameters define both the next actor and the policy used for goal proposal, span classification, and editing. Appendices A and D detail the update rule, GSPO and GiGPO adaptations, and the historical trajectory-averaged objective.

4 EXPERIMENTS

4.1 EVALUATION DESIGN

We use Qwen3-4B-Instruct-2507 (Yang et al., 2025a) and Qwen2.5-7B-Instruct (Yang et al., 2025b) on ALFWorld, WebShop, and ScienceWorld (Shridhar et al.; Yao et al., 2022; Wang et al., 2022). Each round samples up to 16 A tasks with eight trajectories each; auxiliary arms also schedule four B groups of one demonstration and seven new rollouts. ALFWorld uses action-only outputs; WebShop and ScienceWorld use short plans followed by actions. Short-plan experiments use the token-normalized, 256-turn updates in Section 3.5; the action-only ALFWorld results use the trajectory-averaged configuration in Table 8. ALFWorld uses 140 seen development tasks and 134 unseen test tasks; ScienceWorld uses the official 1,796/1,819 development/test split. WebShop uses 1,000 products and synthetic goals, with 500 test tasks; Appendix F specifies monitoring subsets and the earlier full-catalog protocol. SR is the fraction of tasks completed successfully, and score is the mean native reward; both are reported on a $\times 100$ scale.

The primary controls are rerun with the same backbone, original-task stream, training seed 42, and evaluation backend within each comparison. ALFWorld compares all three objectives at round 200; WebShop pairs GRPO at round 80, GSPO at round 60, and GiGPO at round 100; ScienceWorld compares the three GRPO objectives at round 20. Short-plan checkpoints were fixed by common saved-weight availability before test evaluation, without using test scores. RAHL adds B construction and rollouts, so equal A-training rounds do not imply equal total compute. ALFWorld also includes published reference methods, marked separately from the matched reruns; Appendix J gives their sources and protocols.

4.2 ORIGINAL-TASK LEARNING

At round 200, coupled RAHL reaches 91.79% unseen SR, compared with 84.33% for GRPO and 88.06% for decoupled RAHL (Table 1). The ten-task gain comprises five more successes in Look, four in Pick2, and one in Cool; the other categories tie. Seen SR is 94.29% for coupled RAHL versus 88.57% for GRPO; Table 20 gives all split-level counts. These action-only runs test the value of hindsight supervision without plan-text editing.

Development-selected coupled checkpoints reach 92.54% unseen success with Qwen3-4B at round 180 and 93.28% with Qwen2.5-7B at round 95 (Table 22). These development-selected checkpoints complement the fixed-round comparison rather than replacing its common budget; earlier matched ALFWorld and full-catalog WebShop tests remain in Table 23.

On WebShop, GRPO + RAHL completes 371 of 500 tasks, compared with 341 for GRPO at round 80 (Table 2). The 6.00-point SR gain has a paired task-bootstrap 95% interval of [3.00, 9.20] points; mean score also increases from 82.96 to 87.03. The effect depends on the optimizer: at their respective matched budgets, RAHL changes GSPO SR by -0.20 points and GiGPO SR by -1.80 points. Both latter intervals include zero (Table 18); all intervals describe task resampling for one training seed.

On ScienceWorld, coupled RAHL increases GRPO SR from 20.45% to 22.10%, while BC + GRPO reaches 23.09% at the same 20-round budget (Table 3). The coupled gain is 1.65 points, with a paired task-bootstrap 95% interval of [-0.44, 3.74]; mean native scores are -7.49, -5.26, and 2.97 for GRPO, coupled RAHL, and BC + GRPO, respectively.

Figures 3 and 4 show development learning dynamics separately from the fixed-checkpoint tests. For ScienceWorld, GRPO + RAHL rises from 22.27% dev SR at round 20 to 31.64% at round 50, where GRPO reaches 26.95%. On WebShop, the development SR gap narrows from 4.69 points at round

Table 1: ALFWorld success rates (%) with Qwen2.5-7B-Instruct. The GRPO rerun and RAHL use action-only outputs at round 200 on unseen 134; † marks literature references with protocols in Appendix J. Overall is task-weighted SR for these runs and the reported aggregate for †.

GRPO + RAHL	20	-5.26	22.10
RAHL (BC + GRPO)	20	2.97	23.09

80 to 0.78 points at round 120. The continued ScienceWorld improvement motivates evaluation at larger training budgets.

4.3 How should a successful seed enter learning?

Coupled and decoupled RAHL share the construction procedure and scheduled B capacity, but their online data diverge as their policies change. At round 200, coupled RAHL exceeds decoupled RAHL by 3.73 points on ALFWorld unseen tasks, while decoupled RAHL leads by 1.43 points on seen tasks. On ScienceWorld at round 20, BC + GRPO instead leads coupled RAHL by 0.99 points (Table 3); Appendix D analyzes how the two objectives weight the seed and new rollouts.

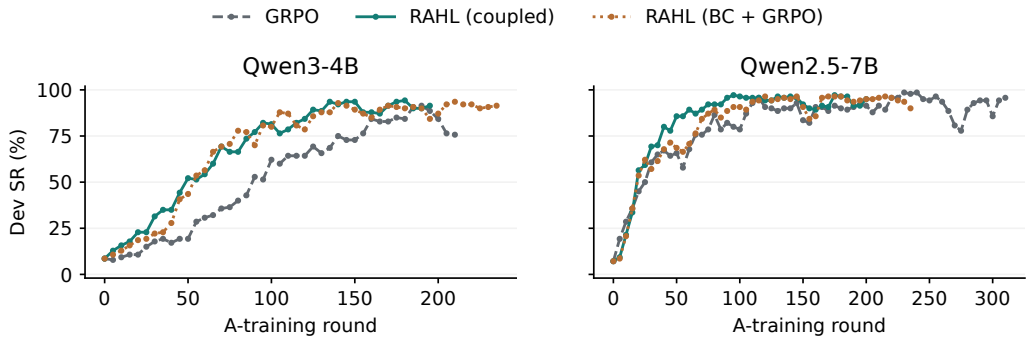

Figure 3: ALFWorld development SR for action-only policies (training seed 42). Points are recorded evaluations on the 140 seen tasks; resumed runs follow checkpoint lineage, and curves stop at their recorded endpoints.

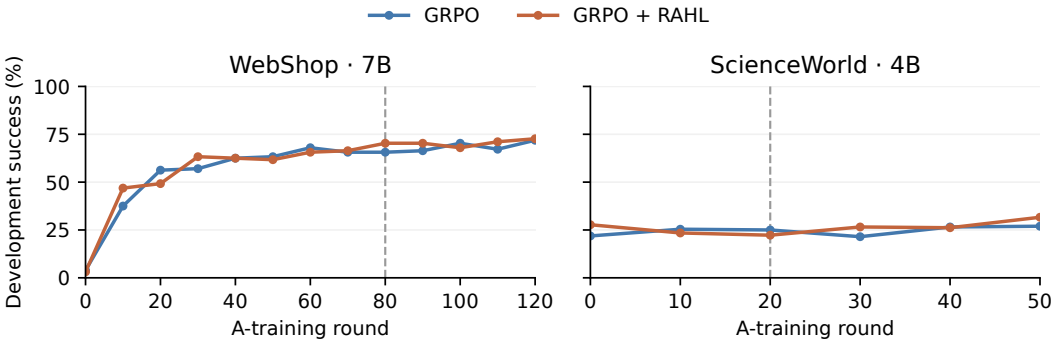

Figure 4: Short-plan development SR for GRPO and GRPO + RAHL on WebShop (7B, 128 tasks) and ScienceWorld (4B, 256 tasks). Each panel ends at the latest round observed for both methods; dashed lines mark the checkpoints used for the separate full-test evaluations. Curves connect recorded evaluations without smoothing; resumed prefixes follow verified checkpoint lineage. Each curve retains its measured initialization.

Replay-verified B groups are effective when fewer than seven new attempts succeed; all-success groups are skipped. For 4B ALFWorld through round 115, 123 of 460 scheduled slots are effective (26.74%). Appendix G separates construction failures from selected groups that supply no update, and reports the archived cross-environment counts.

4.4 What does plan repair change?

A recorded WebShop case changes a plan from checking "noon blue and 3x" to checking "a-blue and 3x-large," matching the attributes actually purchased while preserving the action sequence (Appendix K). The repaired seed succeeds on the relabeled task although all seven newly sampled rollouts fail, illustrating the complementary value of retaining an executed success. A round-10 development control compares repaired and restored original plans under the same GRPO construction procedure (Table 4); the difference is one task out of 128. An additional case still names the wrong product after editing despite successful replay (Table 30), showing that execution verification and plan correctness are distinct.

4.5 How does the relabeler evolve?

We compare the initial model and the round-80 WebShop GRPO + RAHL policy as relabelers on the same 64 eligible histories. With grammar, verification, candidate budgets, and decoding fixed, the number of sources yielding a replay-verified demonstration increases from 32 to 36 (50.00% to

Table 4: WebShop plan-text control with Qwen2.5-7B at round 10, evaluated on the fixed 128-task development subset. Both arms construct and select demonstrations identically; the control restores source plans before learning.

Demonstration plans	Score	SR	Successes
Repaired	65.79	46.88	60/128
Original	66.50	46.09	59/128

56.25%; Table 5). Native-valid candidates increase from 32 to 37, while model calls increase from 307 to 346; verified demonstrations per 100 calls remain similar at 10.42 and 10.40. This fixed-input comparison measures changes in supervision construction through the shared policy, rather than the effect of collecting different trajectories.

Table 5: WebShop relabeler diagnostic on 64 fixed eligible histories with Qwen2.5-7B. Valid B counts all native-accepted candidates; verified counts sources yielding a selected demonstration that passes replay.

Relabeler	Round	Valid B	Verified sources	Model calls
Initial	0	32	32/64	307
Trained	80	37	36/64	346

5 Conclusion

RAHL selects achieved goals together with the plan edits needed to reuse the policy's own behavior as supervision. The edit mask restricts changes to text classified as goal-specific intentions, while environment checks and replay verify the retained execution. The policy learns from these demonstrations and new rollouts, then constructs subsequent supervision with its updated parameters. Matched-round experiments show the clearest gains with GRPO on ALFWorld and WebShop, while the preferred learning objective and optimizer vary across environments. Fixed-source comparisons show greater verified-demonstration coverage after training, with similar yield per call; longer-budget evaluation can test how this recursive construction develops further. These results also define the current boundary of the evidence. The ALFWorld headline uses action-only outputs, so it isolates reuse of achieved behavior rather than plan repair. In the short-plan environments, the optimizer-dependent WebShop comparisons and the ScienceWorld BC result show that RAHL does not dominate every update rule. The fixed-source RSI diagnostic measures construction yield under a shared input cohort; it does not isolate the causal contribution of online relabeler updates or assess semantic text quality. The qualitative failure case further shows that replay verification can accept a physically successful trajectory with an incorrect plan description. Independent training seeds, a frozen-relabeler online control, and longer common budgets are needed to test whether the observed gains persist as the actor–relabeler loop scales. Across these comparisons, the central distinction is between reusing an executed outcome and generating a new successful trajectory. RAHL retains the former while exposing the latter to the current policy's variation. The positive matched comparisons therefore support complementary hindsight supervision, rather than a claim that every relabeled rollout is useful. The negative optimizer comparisons identify where repairability-aware selection alone is insufficient. This separation motivates evaluating goal selection, plan repair, and policy optimization as coupled but independently testable components.

APPENDIX

A ALGORITHM AND INFORMATION INTERFACES

Algorithm 1 freezes the policy for A collection, goal proposal, span classification, plan editing, and new B rollout collection. Sources with native reward below one are shuffled; WebShop requires a valid purchase prefix, and ScienceWorld prioritizes sources with public event evidence. After collection and scoring, the actor takes sequential optimizer steps on global minibatches of 256 assistant-turn records. Construction allows at most 16 source attempts, two proposals per source, 96 model requests, and four selected B groups.

Algorithm 1 Repairability-aware hindsight learning (current protocol)

for each training round k **do**
  Freeze current policy π_k for collection, construction, and scoring
  Collect eight trajectories per A task; retain native rewards and A groups
  Filter and shuffle sources with $R_A^{\text{native}} < 1$; prioritize ScienceWorld events; set $\mathcal{S} = \varnothing$
  for each source, up to 16 attempts **do**
    Propose at most two typed B goals from public history using π_k
    Verify contracts and retain their first successful physical prefixes
    Classify spans, edit chronologically, and enforce the protected-span mask
    If no native-valid relation bucket exists, continue; otherwise sample one uniformly
    If its repairable set is empty, continue
    Select a minimum-edit candidate, breaking ties uniformly
    Add a nonduplicate reset/goal pair to $\mathcal{S}$; stop at $|\mathcal{S}| = M = 4$
  end for
  for each selected B in $\mathcal{S}$ **do**
    Replay its seed and sample seven new attempts in independent sessions
    Reject B if seed replay fails or the eight reset hashes differ
    Set $L_B = 0$ if all seven new attempts succeed
    Otherwise use the chosen backend (Appendix D.5) or BC + GRPO
  end for
  Score retained outputs with π_k; fix rewards, advantages, and references
  Form token-weighted losses with scheduled denominator M
  Shuffle turns, balance within global 256-turn minibatches, and update (Eq. (17))
  Use the updated policy for acting and construction in the next round
end for

The relabeler reuses the actor's parameters until all construction and new sampling for the round finish. A new cache for relabeler calls is created each round; its key hashes the request, including the role-specific task field. The actor loss updates the shared parameters; proposal, classification, and editing responses have no separate training loss.

Table 6: Information access by role. Current action labels, future observations, and private state are excluded from the editor's input.

Role	Public input	Additional access	Output
Proposer	Source trace, goal grammar	Public event summary	B and evidence steps
Editor	B, observation, spans, repaired past	Editable-span mask	KEEP or replacement
Span classifier	Original plan spans	No target goal or state	Editable-span mask
Native verifier	Contract and execution	State or receipt	Success and first hit
Actor	Goal and public history	Action interface	Plan/action or action

A constructed instance stores A, the source trace, typed B, the native witness, first-hit index, edit record, and replayed seed. The actor receives the rendered instruction and public history, while entity bindings, private state, and verification explanations remain in the audit record. Policy, tokenizer, environment, reset, and goal identifiers link each instance to its generation and evaluation records.

Invalid proposals, failed editing checks, and exhausted construction budgets reject candidates while retaining A learning. Replay mismatches in actions, observations, native success, available state hashes, or the first successful step reject the selected B group; all eight sessions must share the same initial-state hash. A seed extending beyond the first-hit boundary, a response exceeding the output-token limit, or a token round-trip mismatch raises an error and interrupts the round.

B ACHIEVEMENT CONTRACTS AND ENVIRONMENT ADAPTERS

B.1 ALFWORLD STATE AND EVENT SEMANTICS

ALFWorld goals bind object and receptacle types to native entities using the eight families in Table 7. Repeated variables refer to the same entity, while two-object placement requires distinct objects and one shared receptacle instance. A new trajectory may satisfy the same typed goal with a different entity binding.

Table 7: ALFWorld achievement contracts. I_t denotes placement, P a processing predicate, and Δ a newly achieved fact during the episode.

Goal family	Completion condition
Hold X	$\exists x{:}X : \mathrm{holds}_t(x)$
Place X in/on Y	$\exists x{:}X, y{:}Y : I_t(x, y)$
Two-place X in/on Y	$\exists x, x'{:}X, y{:}Y : x \neq x' \wedge I_t(x, y) \wedge I_t(x', y)$
Clean X	$\exists x{:}X : \mathrm{clean}_t(x)$
Heat X	$\exists x{:}X : \mathrm{hot}_t(x)$
Cool X	$\exists x{:}X : \mathrm{cool}_t(x)$
Processed-place X, Y, P	$\exists x{:}X, y{:}Y : P_t(x) \wedge I_t(x, y)$
Process-then-place X, Y, P	$\exists x{:}X, y{:}Y, 1 \leq u < v \leq t : \Delta P_u(x) \wedge \Delta I_v(x, y)$

Current-state predicates follow the pinned environment domain, including the removal of cool after heating and of hot after cooling. An object heated and then cooled satisfies a historical heating event but not a current-state hot condition. Process-then-place requires a new processing fact and a later new placement fact for the same object; facts present at reset are not new events.

The structured proposer receives public events extracted from executed actions and their observed success feedback. A cleaning event requires cleaning feedback, rather than the word `clean` appearing in a task instruction. The verifier checks the complete native contract, and public evidence must support the proposal by its first-hit boundary. ALFWorld uses the original task template to help classify candidates as subgoals, alternatives, or incidental achievements. Candidates matching the original ALFWorld task template are excluded; WebShop and ScienceWorld reject an instruction identical to the source instruction.

B.2 WEBSHOP PURCHASE SEMANTICS

A WebShop B contract combines product type, public attributes, keyed selected options, a price upper bound, and an actual purchase. It includes a substantive attribute or option in addition to type and excludes product identifiers and action recipes from the instruction. Another product can satisfy the same contract in a new attempt.

Type and attribute checks use pinned components of WebShop's native reward implementation, requiring accepted type and all specified attributes. Options are checked as normalized key–value pairs, distinguishing an offered option from an actually selected one. The price bound comes from public information and is compared with the settlement price using decimal arithmetic. The auxiliary monitor checks all conditions jointly; A archives and evaluation retain the official continuous reward.

A purchase witness links the action, public page, native receipt, session/reset identity, and catalog and price-table versions. The WebShop relation label is supplied by the proposer and recorded separately from native success verification.

B.3 SCIENCEWORLD ACHIEVEMENT SEMANTICS

Autotelic agents in ScienceWorld also study learning through self-generated goals (Teodorescu et al., 2023). ScienceWorld contracts specify holding an object, placing it in or on a destination, changing its phase, or activating it. The proposer uses public object and container nouns; phase targets are solid, liquid, or gas and require public evidence of the resulting state. The adapter replays recorded actions, rejects goals already true at reset, and identifies the first successful prefix. Sources belong to the official training partition, and B instances retain their source task variation and initial state.

C EDITING PROTOCOL AND SELECTION PROPERTIES

C.1 REQUESTS AND CHRONOLOGICAL STATE

The local editor returns a JSON object with one top-level field, `spans`. Each entry contains exactly `id`, `decision`, `goal_dependencies`, and `replacement`, with lowercase `keep` or `replace` decisions. The program binds each returned identifier to the immutable source-span hash and checks complete span coverage. KEEP restores the original bytes; REPLACE requires text and goal dependencies, and the program restores protected spans even if the editor proposes changes. The accepted plan is appended to the history used at the next step.

Before editing, the policy classifies each source span as goal-specific intent, generic intent, factual or mixed text, or unknown. Classification uses the source spans without the target goal or environment state; only goal-specific intentions receive an editable mask. The program preserves all protected spans, checks complete patch coverage and source hashes, and rejects empty or overlong plans. The program applies the edit mask without a final LLM semantic veto. The editing request omits the current action, and accepted plans satisfy the 192-token limit and an explicit premature-purchase-claim check.

The online original-plan control runs construction and selection, then restores the selected source plans before learning. It retains B, the first-hit prefix, actions, observations, construction calls, and the coupled learning objective.

C.2 PHYSICAL-PREFIX INVARIANCE

Proposition 1 (Physical-prefix invariance)**.** *Assume transitions and physical observations are independent of the task instruction. Couple two executions to the same initial state and environment randomness. If their actions agree through t_B, their states and physical observations agree through that step, even when their goal fields and non-executed plans differ.*

Proof. Write $s_{t+1} = F(s_t, a_{t+1}, \xi_{t+1})$ and $o_{t+1} = O(s_{t+1}, \zeta_{t+1})$. The initial state is shared. Equality at step t, the common action, and coupled randomness give the same next state and observation. Induction establishes equality through t_B. □

The proposition concerns fixed-action replay with task instructions separated from the physical observation payload. Deleting an action while retaining downstream observations or repairing an action during parsing changes that execution record. The relabeler preserves the sequence and checks action/observation hashes before and after plan editing.

ScienceWorld canonicalizes contiguous simulator listing lines at the same indentation, using the same observation function for A, B, and evaluation. Replay requires equal full initial-state hashes, matching canonical observations, and equal successor-state hashes after removing continuous `temperatureC` fields. Full temperature-bearing hashes remain in the audit record; native success and the first-hit boundary are checked separately. Prefixes containing the goal-dependent `task` query are rejected.

C.3 MEANINGFUL CHOICE AND EDIT COST

Fix a source, relation bucket, and edit outcomes with nonempty $\mathcal{F} \subseteq \mathcal{N}$. Native-uniform retains a candidate with probability $|\mathcal{F}|/|\mathcal{N}|$, while repair-uniform always selects one from $\mathcal{F}$. Conditional

on retention, both rules are uniform over $\mathcal{F}$; different retention rates can still change the mixture across sources and buckets. Deduplication and replay checks follow selection, so these probabilities describe candidate retention before training admission. Edit-cost ranking can change the selected goal only when several repairable candidates have different costs.

Edit cost sums inserted and deleted tokens in each plan under the backbone tokenizer; token alignment uses SequenceMatcher with its automatic junk heuristic disabled. The current selector minimizes this cost within the chosen repairable set and samples uniformly among ties.

D Loss reductions and shared-action analysis

D.1 Probability references and token reductions

Before optimization, the frozen round actor rescores every training history to define the old-policy probabilities used by clipping. For the seed, these reference probabilities are computed on its repaired B history. New-rollout generation probabilities are retained as diagnostics; the actor-rescored probabilities enter the loss. Rewards, advantages, reference probabilities, and masks stay fixed across the round's sequential minibatches. Rescoring a demonstration under B defines its clipping reference; it does not correct for having generated the original actions under A.

Token reduction and reward normalization are explicit choices in language-model policy optimization (Yu et al., 2026; Liu et al., 2025). The current protocol scores response tokens from actions, plans, formatting, and EOS, excluding prompts, environment observations, and padding. Let N_A count all A output tokens, n_i the output tokens of B trajectory i, $N_g = \sum_{i=0}^{7} n_i$, and $N_F = \sum_{i=1}^{7} n_i$. With $\phi_u(a) = -\min(\rho_u a, \mathrm{clip}(\rho_u, 1-\epsilon, 1+\epsilon)a)$, the round objectives are

$$L_A = \frac{1}{N_A} \sum_{u \in A} \left[\phi_u(a_u) + \beta_{\mathrm{KL}}(e^{d_u} - d_u - 1) - \beta_H H_u \right], \tag{7}$$

$$L_B^{\mathrm{cpl}} = \frac{\eta \sum_{u \in \tau_0} \phi_u(\hat{a}_0) + \sum_{i=1}^{7} \sum_{u \in \tau_i} \phi_u(\hat{a}_i)}{N_g}, \tag{8}$$

$$L_B^{\mathrm{dec}} = -\frac{\alpha}{n_0} \sum_{u \in \tau_0} \log \pi_\theta(y_u \mid h_u) + \frac{1}{N_F} \sum_{i=1}^{7} \sum_{u \in \tau_i} \phi_u(\widetilde{a}_i), \tag{9}$$

$$L_{\mathrm{round}} = L_A + \frac{\lambda_B}{M} \sum_{g \in \mathcal{S}} L_{B,g}. \tag{10}$$

D.2 Sample-normalized binary advantages

For GRPO, we subtract the group mean reward and divide by the sample standard deviation, using Bessel's correction and a 10^{-6} floor. A and coupled B use eight trajectories; the decoupled new-rollout advantages use only the seven new trajectories. If $k < 7$ new attempts succeed, $p = (k+1)/8$, the seeded group's standard deviation is $\sqrt{8p(1-p)/7}$, and its success and failure advantages are $\sqrt{7/8}\sqrt{(1-p)/p}$ and $-\sqrt{7/8}\sqrt{p/(1-p)}$. When all seven new attempts fail, the advantages and the coefficient that would match the direct seed gradient at an initial ratio of one are

$$\hat{a}_0 = \frac{7}{\sqrt{8}}, \qquad \hat{a}_{1:7} = -\frac{1}{\sqrt{8}}, \qquad \alpha_{\mathrm{match}} = \eta \frac{7}{\sqrt{8}} \frac{n_0}{N_g}. \tag{11}$$

The implementation keeps $\alpha = 0.16535945694153692$ as a fixed hyperparameter; it does not impose Equation (11)'s length-dependent match. For equal lengths and $\eta = 0.5$, the matching value would be approximately 0.15468. All-new-failure groups have zero decoupled new-rollout advantages, leaving only the seed cross-entropy in that arm. If all seven new attempts succeed, both B objectives are set to zero, including seed cross-entropy.

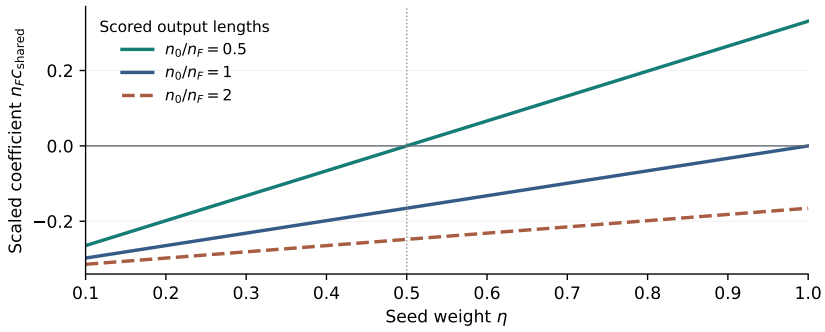

Figure 5: Historical r6 shared-action coefficient from Equation (13), scaled by new-trajectory length. The curves use population-standardized advantages and per-trajectory token means; the current total-token reduction instead gives Equation (12).

D.3 Shared-context token contributions

For the GRPO objective at the initial ratio of one, consider one occurrence of the same output token at the identical full conditioning history in each of the eight B trajectories. Since $\sum_{i=0}^{7} \hat{a}_i = 0$, its whole-group coupled ascent coefficient, before the common λ_B/M factor, is

$$c_{\text{shared}} = \frac{\eta\hat{a}_0 + \sum_{i=1}^{7} \hat{a}_i}{N_g} = \frac{(\eta - 1)\hat{a}_0}{N_g}. \tag{12}$$

For an effective binary B group, $\hat{a}_0 > 0$, so this coefficient is negative when $\eta < 1$, regardless of the length ratio. The coefficient multiplies the common log-probability gradient; other contexts and A terms also contribute to learning. A minibatch may contain only some of these occurrences, and later minibatches use updated parameters, so the expression does not determine each sequential step's sign.

D.3.1 Historical r6 length dependence

The historical r6 protocol uses population-standardized advantages and averages token losses within each trajectory before averaging the eight trajectories. A uses the same trajectory means, averaged within each group and then across the actual A groups; primary r6 runs take one optimizer step per round. If all new attempts fail and have common length n_F, its shared-token coefficient and decoupled seed contribution are

$$c^{\text{r6}}_{\text{shared}} = \frac{\sqrt{7}}{8}\left(\frac{\eta}{n_0} - \frac{1}{n_F}\right), \qquad c^{\text{r6}}_{\text{dec}} = \frac{\alpha}{n_0}, \qquad \alpha = \frac{\eta\sqrt{7}}{8}. \tag{13}$$

$$\ell_i(a) = \frac{1}{n_i}\sum_{u \in \tau_i} \phi_u(a), \tag{14}$$

$$L^{\text{r6}}_{B,\text{cpl}} = \frac{1}{8}\left[\eta\ell_0(a_0^{\text{pop}}) + \sum_{i=1}^{7} \ell_i(a_i^{\text{pop}})\right], \tag{15}$$

$$L^{\text{r6}}_{B,\text{dec}} = \alpha\,\text{CE}_0 + \frac{1}{7}\sum_{i=1}^{7} \ell_i(\tilde{a}_i^{\text{pop}}). \tag{16}$$

D.4 Regularization and sequential minibatches

GRPO and GiGPO use $\rho_u = \exp(\text{clip}(\log \pi_\theta - \log \pi_{\text{old}}, -20, 20))$ and $\epsilon = 0.2$. The reference penalty uses $d_u = \text{clip}(\log \pi_{\text{ref}} - \log \pi_\theta, -20, 20)$, with the initial backbone as the frozen reference.

Here H_u is next-token entropy; all current domains use $\beta_{\mathrm{KL}} = 0.01$, with $\beta_H = 0.001$ for WebShop and zero otherwise. These terms enter only A's total-token reduction; B uses its auxiliary objective alone.

Missing, replay-rejected, and all-new-success B groups contribute zero under the fixed scheduled denominator $M = 4$. Let T count output tokens in the retained training rows and T_m count their tokens in minibatch m, across workers and without padding. Each global 256-turn minibatch takes one optimizer step using the restricted round objective and the following scale. Real assistant-turn records are shuffled before forming minibatches and balanced by length only within each minibatch; zero-weight padding is confined to the last batch. Each worker multiplies its loss by the data-parallel world size to compensate for FSDP gradient averaging.

$$L_m(\theta_m) = \frac{T}{T_m}\, L_{\mathrm{round}}(\theta_m)|_{u\in m}\,, \qquad \theta_{m+1} = \mathrm{AdamWStep}(\theta_m, \nabla L_m). \tag{17}$$

Zero-weight B rows are removed before minibatching, including all-new-success groups and the decoupled new rows of all-new-failure groups. Thus the two arms can differ in T, minibatch composition, and optimizer-step count even with the same scheduled B capacity. Equation (11) compares the direct seed terms of the initial whole-group objectives; sequential updates additionally depend on these minibatch scales.

D.5 Optimizer adaptations

Let T_i be the number of executed turns and v_{it} indicate an invalid action; A training uses

$$R_i^A = q_e(R_i^{\mathrm{native}}) - \frac{c_e}{T_i}\sum_{t=1}^{T_i} v_{it}, \quad q_e(r) = \begin{cases} \mathbf{1}[r \geq 1] & \text{ALFWorld,} \\ 10\,\mathbf{1}[r \geq 1] & \text{WebShop,} \\ r & \text{ScienceWorld.} \end{cases} \tag{18}$$

The coefficients c_e are 0.1, 0.2, and 0.5 for ALFWorld, WebShop, and ScienceWorld; B uses $r_i \in \{0, 1\}$ without this penalty. Source eligibility and reported scores use native rewards before these transformations.

For GSPO, one assistant response is the sequence unit. Let ℓ_{it} be its output-token count and $\Delta_{itu} = \log \pi_\theta(y_{itu} \mid h_{itu}) - \log p_{itu}^{\mathrm{old}}$. The GSPO-token implementation uses the following ratio, where sg stops gradients:

$$\bar{\Delta}_{it} = \frac{1}{\ell_{it}}\sum_{u=1}^{\ell_{it}} \Delta_{itu}, \tag{19}$$

$$\rho_{itu}^{\mathrm{GSPO}} = \exp\big(\min\{10, \mathrm{sg}(\bar{\Delta}_{it}) + \Delta_{itu} - \mathrm{sg}(\Delta_{itu})\}\big)\,. \tag{20}$$

We substitute this ratio into the surrogate with bounds $1 - 0.0003$ and $1 + 0.0004$, keeping episode advantages and the token denominators in Eq. (10). Because each response has a constant advantage, the token sum has the same gradient as a response-ratio loss weighted by response length.

For GiGPO, let $\mathcal{I}_g(o)$ contain all turn occurrences with the exact pre-action public observation o within one A or B group g. Write a_i for the group's standardized episode advantage and $Q_{it} = \sum_{s=t}^{T_i} d_{is}$ for its undiscounted return; with singleton state advantages set to zero, define

$$b_{it} = \frac{Q_{it} - \mathrm{mean}_{(j,s)\in\mathcal{I}_g(o_{i,t-1})}\, Q_{js}}{\max\{\mathrm{SD}_{\mathrm{sample}}(Q_{js} : (j,s) \in \mathcal{I}_g(o_{i,t-1})), 10^{-6}\}}, \qquad a_{it}^{\mathrm{GiGPO}} = a_i + b_{it}. \tag{21}$$

For ScienceWorld A, d_{it} is the native score increment minus $c_e v_{it}/T_i$; for other A tasks, the success reward is placed at the final turn and the same penalty is applied at each invalid turn. B places its binary reward at the final turn. We use state weight one and replace a_i by a_{it}^{GiGPO} for every output token in that turn. The seed weight η, group capacity M, all-success skip rule, A-only regularization, and minibatch scaling remain unchanged; BC + GRPO is the GRPO-only update control.

Table 8: Historical r6 action-only configuration, retained for the archived results in Appendix G.4. Each environment and backbone is trained separately; the listed budgets are planned endpoints, and recorded traces stop at their actual checkpoints.

Parameter	Value
Backbones	Qwen3-4B-Instruct-2507; Qwen2.5-7B-Instruct
Optimizer	AdamW; lr 10^{-6}; $\beta = (0.9, 0.999)$; constant LR, no warmup
Weight decay / gradient norm	0.01 / 1.0
Policy clip / epochs	0.2 / one epoch
Main optimizer schedule	One step per A-training round
A groups / trajectories	16 tasks per full round; eight trajectories per task
Scheduled B groups	Four for auxiliary methods; zero for A-only
Source / construction limits	$R_A < 0.5$; 32 sources; at most four candidates per source
History / thinking	Last five turns, trimmed further to fit; thinking disabled
Actor prompt / output	ALFWorld and WebShop 12,288 / 2,048; ScienceWorld 7,000 / 512 tokens
Actor sampling	Temperature 1; top-$p = 1$; no top-k truncation
Relabeler prompt / output	16,384 / 2,048 tokens; temperature 0.7; four-source prefetch
Episode horizon	ALFWorld 50; WebShop 20; ScienceWorld 30 actions
ScienceWorld environment	Version 1.2.2; official task splits; easy simplification
Auxiliary coefficients	$\lambda_B = 0.25$; $\eta = 0.5$; $\alpha = 0.16535945694153692$
A regularization	KL 0.01; entropy 0.001
Precision	FP32 master/state; BF16 forward and vLLM; FP32 reduction
GPU microbatch token budget	16,384; gradient checkpointing and padding removal enabled
vLLM capacity	Context 18,432; batched tokens 32,768; max sequences 256
Training budget	Three passes: ALFWorld 669, WebShop 1,986, ScienceWorld 675 rounds
Checkpoint / monitoring	4B every round, 7B every five; greedy dev every five rounds
Seed / selection metric	Training seed 42 for development traces; mean native dev score

E Implementation and training configuration

Each Instruct backbone receives full-parameter updates from its original weights, without a project-specific supervised warm-up. The implementation uses a frozen verl-agent stack built on verl/HybridFlow (Sheng et al., 2025), with Ray, FSDP actor/reference workers (Zhao et al., 2023), and colocated vLLM generation (Kwon et al., 2023). AdamW (Loshchilov & Hutter, 2017) uses FP32 master parameters and optimizer states, BF16 forward computation, and FP32 gradient reduction. Each run uses eight GPUs, two tensor-parallel generation replicas of size four, and 128 environment slots. Table 8 records the earlier r6 action-only protocol; Table 9 gives the r13 short-plan configurations.

Archives and evaluation retain native rewards: the official continuous WebShop score and the ScienceWorld score divided by 100, including negative values. Training annotation alone applies the transformations in Table 9 before computing A advantages. Source selection compares the archived native reward with one before this transformation.

Current r13 runs use static microbatches of one assistant response, actor-parameter offloading, and a vLLM GPU-memory fraction of 0.35. All deployments retain global minibatches of 256 assistant-turn records and one optimizer epoch per collection round. These deployment settings are recorded with each run, separately from the historical r6 microbatch budget.

The current actor sees the observation and up to five preceding interaction turns; the prompt builder first drops old history, then trims the middle of the current observation and the command list if needed. Omission markers identify trimmed content, and an overflow error is raised if the remaining prompt still exceeds its budget. Short-plan outputs use `<plan>`text`</plan><action>`action`</action>`, with a hard 192-token plan limit; only the action field is executed. Collection, seed scoring, and evaluation share the interface within each comparison. Historical r6 curves use action-only outputs; its optional short-plan interface has a 96-token plan limit.

Table 9: Current short-plan configurations; ν is the fraction of invalid actions in an episode. The r13 protocol uses masked editing and native replay checks; reward transformations apply only to training. The training target is 200 rounds; each performance comparison reports its actual common checkpoint budget.

Parameter	WebShop (1k synthetic)	ScienceWorld
Interface / plan limit	Short plan + action; hard limit 192 plan tokens	
A batch / B capacity	Up to 16 A tasks $\times 8$; $M = 4$ B groups	
Source / candidate caps	$R_A^{\text{native}} < 1$; 16 sources; two candidates per source	
Selection	Minimum edit cost in selected bucket; uniform ties	
Loss / updates	Token means; sample SD; sequential global 256 turns	
Auxiliary coefficients	$\lambda_B = 0.25$, $\eta = 0.5$, $\alpha = 0.16535945694153692$	
Optimizer / clipping	AdamW, lr 10^{-6}, $\beta = (0.9, 0.999)$; GRPO/GiGPO clip 0.2	
Weight decay / grad norm	0.01 / 1.0; one epoch, constant LR, no warmup	
A train reward	$10\mathbf{1}[R_A^{\text{native}} \geq 1] - 0.2\nu$	$R_A^{\text{native}} - 0.5\nu$
KL / entropy	0.01 / 0.001	0.01 / 0
Actor prompt / output	12,288 / 2,048 tokens	7,000 / 512 tokens
Horizon / evaluation	20 actions; greedy	30 actions; greedy
Training decoding	Temperature 1; top-$p = 1$; no top-k truncation	
Construction decoding	Proposal temperature 0.7; classifier/editor greedy	
Construction budgets	Context 16,384; proposal output 2,048; classify/edit output 1,024	
Calls / prefetch	At most 96 requests per round; four sources prefetched	
Environment	1,000 products; official search/scorer	Version 1.2.2; easy simplification
Target / monitoring	200 rounds; dev every 10	200 rounds; dev every 10
Save / monitor size	Every 20 rounds and dev best / 128	Every 20 rounds and dev best / 256

Table 10: Historical r6 splits; the full/human WebShop track also uses these partitions. Derived B instances remain in their source partition.

Partition	ALFWorld	WebShop	ScienceWorld
Train	3,553	10,587; IDs 1,500–12,086	3,592
Development	valid_seen: 140	1,000; IDs 500–1,499	1,796
Monitoring	All 140	Fixed 256 goals	Fixed 256 tasks
Test	valid_unseen: 134	500; IDs 0–499	1,819

Task streams shuffle each protocol's training pool without replacement and retain the final partial batch of every pass. The paired main arms share the original-task sequence. Checkpoints contain actor, optimizer, random-number and driver states, task cursors, and recorded cost counters. Continuations inherit their parent's training seed and checkpoint and constitute the same training lineage. Branch selection uses recorded evaluation progress, then checkpoint progress and parent priority for ties, without consulting score.

The r13 ALFWorld runs also use 256-turn token-normalized updates, with a 50-action horizon and a training reward of $\mathbf{1}[R_A^{\text{native}} \geq 1] - 0.1\nu$. Their prompt and response limits are 7,000 and 512 tokens, respectively; entropy regularization is zero. GRPO, GSPO, and GiGPO share the same construction pipeline and token reductions; GSPO uses an assistant response as its sequence unit, with ratio clipping to $[0.9997, 1.0004]$ (Zheng et al., 2025). This GSPO adaptation retains stream-token weighting rather than averaging sequence losses equally. GiGPO groups identical pre-action observations within each task and goal, using state weight one and $\gamma = 1$ (Feng et al., 2026). For GiGPO, ScienceWorld A groups use native score increments; other A groups use terminal success rewards, and penalties are assigned to invalid steps. B groups use their terminal binary rewards.

F Evaluation and annotation protocol

F.1 Splits, selection, and statistics

The current WebShop track uses 1,000 products with synthetic goals, official Lucene/spaCy search and scoring, and environment seed 1. Its partitions contain 5,410 training, 1,000 development, and

Table 11: Plan-error categories for interpreting the natural cases in Appendix K. Physical verification checks the executed trajectory; these categories concern the accompanying text.

Category	Decision criterion
Stale goal	Treats an obsolete A requirement as required by B
Unsupported fact	Asserts a fact unsupported by the public prefix
False completion	Claims progress before it occurs
Intent/action conflict	Revised intention contradicts the action
True fact lost	Removes a supported fact relevant to B
Cross-step conflict	Contradicts previously accepted plans or public observations

500 test goals; a fixed 128-goal development subset monitors training. Two test goals duplicate training content, so the protocol retains the primary 500-goal evaluation and specifies a 498-goal sensitivity evaluation excluding them. These results are reported separately from full/human WebShop results.

For development-selected results, mean native development score selects checkpoints within each protocol. ALFWorld uses all 140 seen tasks; full/human WebShop and ScienceWorld use 256-task development monitors, while 1k WebShop uses 128. Checkpoint selection precedes held-out testing, and fixed-round budgets are reported separately from development-selected checkpoints. For short-plan comparisons, a common saved checkpoint was fixed at 13:30 on September 26, 2026, before held-out testing: the largest complete 20-round multiple shared by the primary pure/coupled pair; optional objectives enter only at that same round. Historical development pairwise tables align the latest common recorded round, and three-arm tables require a round recorded by all three arms.

SR is the fraction of tasks whose native reward reaches one; score averages raw native rewards, including ScienceWorld values of -1. Recorded development results and the separately identified historical held-out checkpoints use training seed 42 and report single-run values on the $\times 100$ scale. Fixed-budget tables report individual runs at training seed 42; development-selected checkpoints are labeled separately. For the current short-plan tests, 10,000 paired task-bootstrap resamples give percentile intervals for fixed-policy differences (Efron, 1979); these do not measure training-seed variability.

Compared policies share greedy decoding, context and response limits, and episode horizons within each protocol. Current evaluation uses the trimming rules in Appendix E; historical r6 removes old history only and raises an error if the goal and current observation still exceed the limit. Every reported evaluation covers its complete fixed task set.

In the historical r6 records, initialization evaluations agree across ALFWorld and WebShop arms within each backbone. ScienceWorld starts differ across those runs on the same ordered task list, so the historical curves retain each run's measured starting point. Native-score plots include the full observed negative range. Current short-plan development curves also retain their measured starting values, which differ across runs despite the same nominal backbone.

F.2 Fixed-source construction diagnostic

The diagnostic uses 64 histories sampled uniformly with seed 20260926 from 175 eligible WebShop sources in the first ten recorded rounds of the 7B GRPO + RAHL run. Eligibility is determined by native reward below one and the valid purchase-prefix prefilter, before any proposal or editing outcome is known. The initial and trained relabelers receive this same cohort; measured yields are conditional on these eligible sources.

F.3 Goal yield and relabeler evolution

Valid-goal yield is the number of native-accepted candidates divided by the 64 fixed sources. Verified-demonstration yield is the fraction of these sources that produce a selected demonstration passing seed replay. Sources that produce no accepted goal, fail editing, or fail replay remain in both denominators. Calls and input/output tokens measure construction cost; these automatic checks do not label semantic errors in the plans.

Table 12: Hindsight construction and reuse in HSL, LfH, ECHO, and RAHL (Li et al., 2026b; Xu et al., 2026; Hu et al., 2025). Entries describe each method's published mechanism; benchmark-specific implementations can differ.

Method	Construction	Learning or reuse
HSL	Achieved goals and retained prefixes	Weighted imitation with action-loss masking
LfH	Instruction relabeling and group re-scoring	Original and hindsight RL on existing rollouts
ECHO	Goal and trajectory-step rewriting	Reusable workflows for memory-based adaptation
RAHL	Goal selection through masked plan repair; fixed execution	Shared actor–relabeler learning with demonstrations and new rollouts

Table 13: Construction cost for the fixed 64-source WebShop diagnostic; these counts cover relabeling calls, not complete training.

Quantity	Initial	Round 80
Model calls	307	346
Input tokens	463,187	517,508
Output tokens	14,462	16,163
Verified demonstrations / 100 calls	10.42	10.40

The initial model and the reported 7B WebShop GRPO + RAHL checkpoint construct supervision from the same fixed source set. Goal grammar, verifier, candidate budget, decoding, and source eligibility remain identical across checkpoints. We compare native-valid goal yield, replay-verified demonstration yield, and model calls on these identical inputs.

G Comparisons and resource accounting

G.1 Matched comparisons

Original-task GRPO shares RAHL's actor, parser, reward, regularization, and main task stream. Fixed-round comparisons match original-task sampling; RAHL additionally constructs goals, replays demonstrations, and samples B rollouts.

LfH relabels existing rollout groups and jointly learns from original and hindsight objectives (Xu et al., 2026). HSL identifies achieved goals, retains prefixes, and trains with action-loss masking and demonstration weighting (Li et al., 2026b). Table 12 compares these construction and learning choices with RAHL.

Published policy-optimization references appear in Table 25, retaining their source protocols. The local GRPO, GSPO, and GiGPO optimizer study in Table 14 uses the historical action-only protocol and is separate from these published values. The round-10 original-plan development control in Table 4 changes the demonstration text used for learning while retaining the construction procedure.

G.2 Cost ledger and learning curves

Figure 6 reports historical fit-loop GPU-hours and generated output tokens; Table 13 gives the fixed-source relabeler costs for the current short-plan diagnostic. Recorded fit-loop GPU-hours multiply elapsed recorded time by eight GPUs, including development evaluation and checkpoint activity. They exclude startup, queue waiting, and work lost after the last recorded state during preemption. Recorded output tokens include actor, relabeler, and development generation, exclude padding requests, and resume from saved counters.

Construction loses supervision when outcomes fall outside the goal language or candidates fail native verification, editing constraints, or replay. In the action-only ScienceWorld snapshot, coupled runs select only four B groups for 4B and two for 7B over their respective recorded windows. Rejected candidates and groups with seven successful new rollouts still consume resources, recorded separately from effective updates in Appendix G.

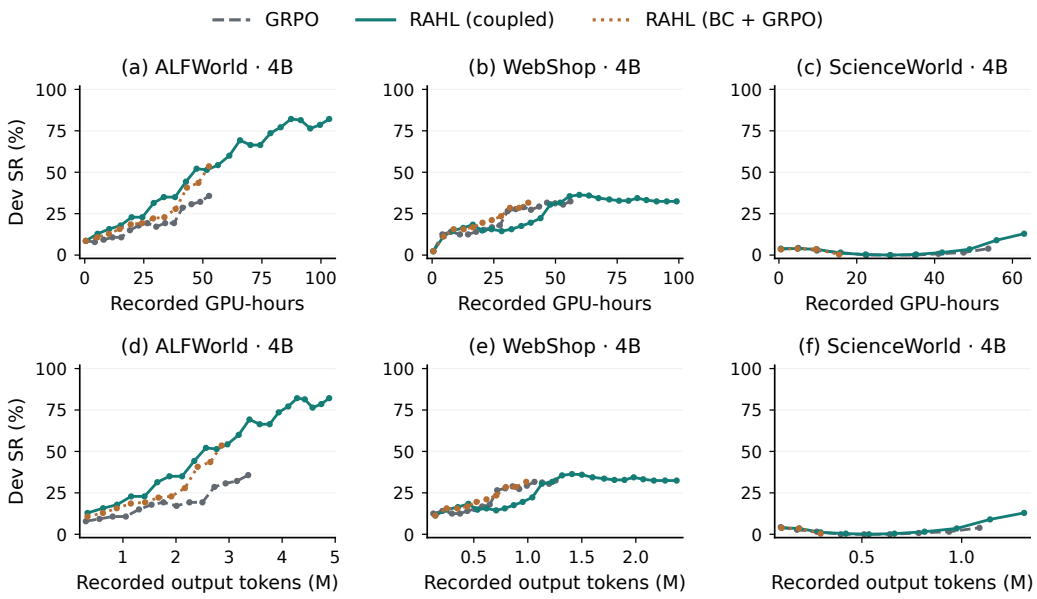

Figure 6: Recorded-resource diagnostics for the historical r6 4B action-only runs. GPU-hours include recorded evaluation and checkpoint time; output tokens include development generation. Unrecorded preemption losses are excluded, so these counters describe the recorded execution.

Table 14: Historical r6 same-round development comparisons under its 256-turn adaptation, using Qwen3-4B and seed 42. Each row compares an algorithm with and without coupled hindsight learning.

Environment	Algorithm	Round	Base SR	+RAHL SR	Base score	+RAHL score
ALFWorld	GRPO	5	7.14	6.43	7.14	6.43
ALFWorld	GSPO	40	38.57	50.71	38.57	50.71
ALFWorld	GiGPO	5	4.29	10.00	4.29	10.00
WebShop	GRPO	5	10.94	10.55	38.94	30.07
WebShop	GSPO	45	32.42	31.25	64.18	61.96
WebShop	GiGPO	55	33.20	32.03	64.54	64.62

Figure 6 plots development SR against these recorded counters. Rejected proposals and skipped all-success B groups remain part of the construction and collection work. The paired task-round comparisons in Table 26 and resource diagnostics answer different budget questions.

G.3 Optimizer adaptations with 256-turn updates

The historical r6 optimizer study pairs GRPO, GSPO, and GiGPO with coupled RAHL on ALFWorld and full/human WebShop using the 4B backbone. All six arms within an environment use global minibatches of 256 assistant-turn records and share task order, initialization, interface, and decoding. Each minibatch takes one optimizer step, retaining episode-token coefficients and scaling by total real rows divided by minibatch real rows. This differs from both r6's one-step-per-round primary runs and the current total-token and token-count-scaled updates.

GRPO uses token ratios with clipping to $[0.8, 1.2]$. The GSPO adaptation (Zheng et al., 2025) uses the exponential mean log-ratio within each assistant response and clips to $[0.9997, 1.0004]$. GiGPO adds a step advantage grouped by exact pre-action observation within the same task, goal, and reset, using $\gamma = 0.95$ and step weight one (Feng et al., 2026). The implementations keep the scheduled B denominator and seed weight of the coupled objective.

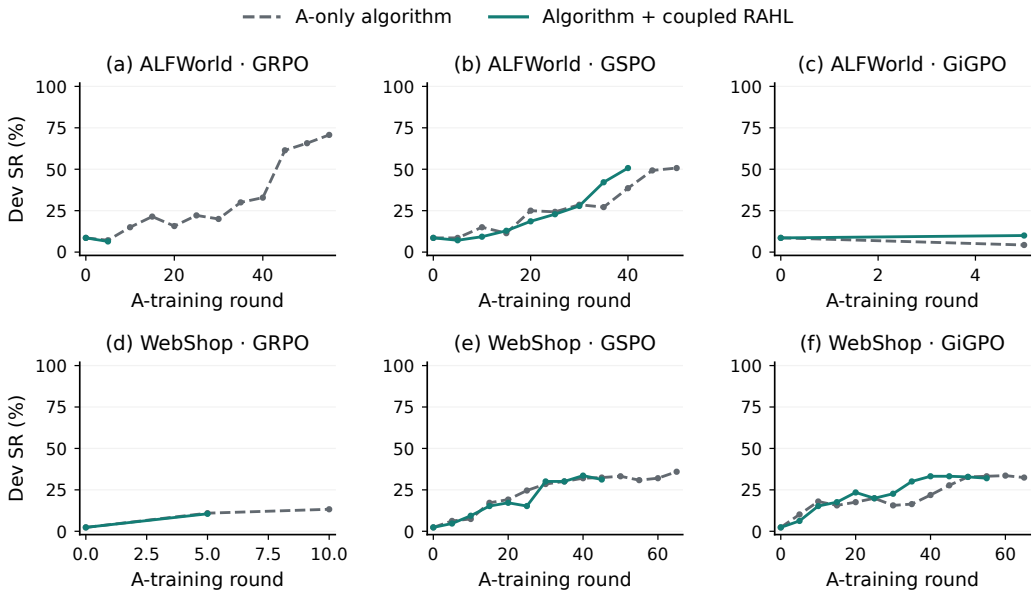

Figure 7: Historical r6 development SR under matched 256-turn optimizer adaptations. All runs use the 4B backbone and seed 42; endpoints follow recorded evaluations.

Table 15: Historical r6 three-arm development comparison at each environment/backbone's latest common evaluated round. Cpl denotes coupled RAHL and BC denotes seed BC with new GRPO; all rows use training seed 42.

Environment	Model	Round	GRPO SR	Cpl SR	BC SR	GRPO score	Cpl score	BC score
ALFWorld	4B	55	28.57	51.43	53.57	28.57	51.43	53.57
ALFWorld	7B	55	57.86	85.71	66.43	57.86	85.71	66.43
WebShop	4B	50	27.73	19.53	31.64	54.12	54.94	59.66
WebShop	7B	40	39.06	36.33	39.06	66.85	65.59	67.34
ScienceWorld	4B	15	1.56	1.17	0.39	2.38	2.20	4.54
ScienceWorld	7B	15	0.00	0.00	0.00	6.05	3.70	7.50

The ALFWorld GSPO pair reaches 38.57 and 50.71 SR at round 40, while WebShop GiGPO and GSPO each lose 1.17 SR points with hindsight at their shared endpoints. The GRPO pairs share evaluations only through round five, so their table entries cover a shorter window. At ALFWorld round 55, A-only GRPO reaches 70.71 SR under 256-turn updates and 28.57 under round updates, indicating sensitivity to the optimization schedule. Figure 7 retains each arm's actual progress.

G.4 Development scores and auxiliary exposure

This subsection retains historical r6 action-only results under the configuration in Table 8. Table 15 aligns all three arms by round, while Figure 8 traces native scores over their recorded training windows. Table 16 separates scheduled slots, selected groups, and effective updates for those runs.

G.5 Recorded achieved-goal constructions

In the recorded ALFWorld interaction, A is "examine the watch with the desklamp."; the 50-action attempt receives reward 0. The achieved goal is "Hold a watch in your inventory.", verified by the first 2 actions; 0 of the seven paired new attempts succeed.

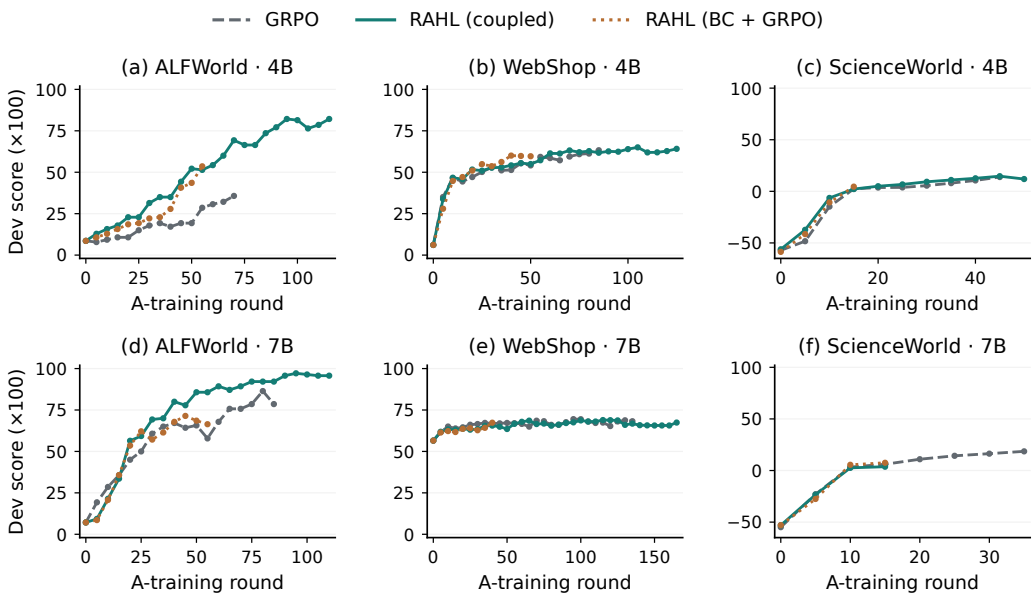

Figure 8: Historical r6 mean native development score ($\times 100$) for the primary action-only runs. ScienceWorld axes include negative rewards; points and endpoints retain each recorded evaluation.

Table 16: Historical r6 auxiliary exposure over each primary run's recorded training window. Through is the last recorded training round; 0/7 and 7/7 count selected groups with zero and seven new successes. Effective equals selected minus 7/7, and scheduled slots include failed construction.

Environment	Model	Arm	Through	Slots	Selected	Effective	0/7	7/7
ALFWorld	4B	Cpl	115	460	456	123	27	333
ALFWorld	4B	BC	57	228	227	93	26	134
ALFWorld	7B	Cpl	110	440	353	104	16	249
ALFWorld	7B	BC	55	220	216	80	7	136
WebShop	4B	Cpl	127	508	149	77	32	72
WebShop	4B	BC	50	200	34	19	14	15
WebShop	7B	Cpl	165	660	106	55	15	51
WebShop	7B	BC	40	160	23	13	5	10
ScienceWorld	4B	Cpl	52	208	4	1	0	3
ScienceWorld	4B	BC	18	72	0	0	0	0
ScienceWorld	7B	Cpl	15	60	2	1	0	1
ScienceWorld	7B	BC	15	60	4	0	0	4

In the recorded ALFWorld interaction, A is "put some pen on shelf."; the 50-action attempt receives reward 0. The achieved goal is "Hold a alarmclock in your inventory.", verified by the first 6 actions; 0 of the seven paired new attempts succeed.

In the recorded WebShop interaction, A is "i need a coconut hair loss serum, and price lower than 30.00 dollars"; the 8-action attempt receives reward 0. The achieved goal is "Buy a lip balm with coconut milk, gluten free, at a price no more than 7.39 dollars.", verified by the first 8 actions; 0 of the seven paired new attempts succeed.

In the recorded ScienceWorld interaction, A is "Your task is to find a(n) living thing. First, focus on the thing. Then, move it to the red box in the kitchen."; the 30-action attempt receives reward 0.25. The achieved goal is "Place banana in or on red box.", verified by the first 8 actions; 5 of the seven paired new attempts succeed.

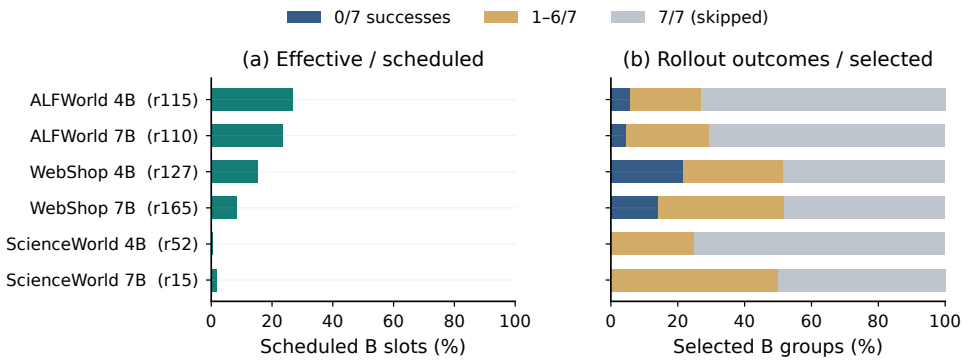

Figure 9: Auxiliary signal in the archived r6 action-only snapshot, by environment and backbone, for coupled RAHL. Left: effective groups per scheduled slot; right: the distribution of new successes among selected groups. Labels give the final recorded round; Table 16 reports counts over each run's observation window.

These cases retain the recorded actions, observations, and outcomes of historical r6 action-only runs. They illustrate prefix construction; the current short-plan protocol additionally applies masked editing to the recorded plans.

H SCOPE AND LIMITATIONS

RAHL relies on an adapter that can verify the outcomes represented by its goal language. The relabeler is restricted to that goal space, and WebShop matching inherits the benchmark's operational type and attribute semantics. Extending RAHL to open-ended environments requires evidence that proposed goals were achieved and a clear separation between task instructions and environment observations. Appendix K includes an execution-verified demonstration whose edited plan names the wrong product.

The same policy proposes goals, classifies spans, and edits plans, so errors can be correlated across roles. Program checks enforce edit permissions and structure; they do not measure semantic correctness. Actor updates affect relabeling through shared parameters without a dedicated relabeler loss; fixed-source diagnostics measure the resulting construction changes. The fixed-source comparison does not isolate the causal effect of updating the relabeler; that requires an online control with a frozen relabeler.

Action-only ALFWorld tests establish the value of hindsight supervision; the short-plan results test the complete system, while the direct plan-text intervention is limited to the development comparison. Changes in loss reduction, update schedule, and WebShop data require comparisons within the same protocol. Different backbone initialization histories make cross-model comparisons robustness checks rather than isolated scaling experiments. Learning to change executed actions or directly optimize the relabeler would extend the action-preserving construction studied here.

I PROMPT TEMPLATES

This section gives the current actor templates, proposal and masked-repair request objects, and separately labeled historical prompts. Double braces denote runtime observations, goals, lists, or previously accepted history. The request objects are inputs to the message builder: fixed examples become user/assistant demonstration pairs, followed by the actual request serialized as JSON. The builder removes the examples field from the actual request, serializes it with `ensure_ascii=False, sort_keys=True`, and disables thinking in the chat template. Source paths, hashes, and extraction records are retained with the author materials.

I.1 ACTOR PROMPTS

For the current actor, concatenate the environment prefix and the selected interface suffix below with one separating space. The user message uses the common template below; repeat the observation/response history block for up to five retained turns and omit its heading when history is empty. The default last-action feedback is `No previous action.`; environment command enumerations are supplied at runtime.

Actor system prefix: webshop

```
You operate a shopping website. Search using the important product
requirements. Inspect product details and select the requested options
before buying. A listed option is not necessarily selected. Compare
all requested attributes and the price. Search syntax is
search[QUERY], with both square brackets required. Replace QUERY with
actual search words from the task. For example, search[blue cotton
shirt] searches for that product. Use a SHORT query: the product type
and two or three distinctive keywords. Check price, size and color on
the item page instead of putting every requirement in the query.
Search results show abbreviated titles, not all product attributes or
options. Open a plausible product by clicking its visible item ID;
inspect its Description, Features and option controls before rejecting
it. An attribute missing from a search-result title is not evidence
that the product lacks it. Do not loop between the same search and
Back to Search. After inspecting an unsuitable item, try a different
item or revise the query. Copy click labels exactly from the visible
controls. Treat the task as catalog requirements, including unusual
combinations of category, size, or fit; inspect the available products
and options before deciding they conflict. Buy only after checking the
requirements; use the search/back controls to find alternatives.
```

Actor system prefix: scienceworld

```
You operate the ScienceWorld laboratory. Follow the task and perform
one physical action at a time. Use exact simulator command and object
wording. A listed command is parseable but may be ineffective or
harmful. Follow required causal ordering and focus on the requested
object when the task asks you to. The command list is incomplete:
other simulator commands may also work. Objects can be in other rooms
or inside containers. Track your inventory, location and object
states. After an action is rejected or has no effect, revise the
command or inspect the state instead of repeating it. The task is
already shown; spend actions on the environment instead of querying
the task again. Never reset the task. A successful action does not by
itself establish task completion.
```

Actor system prefix: ALFWorld

```
You operate in an ALFWorld household. Follow the task using physical
actions. Use exact visible object and receptacle names. Inspect and
open containers to find objects; take an object before placing,
cleaning, heating or cooling it. Use the relevant appliance for
heating or cooling and a sink for cleaning. Track your location and
inventory. After a rejected action, inspect the available commands.
```

Action-only system suffix

```
Reply with exactly one environment action, without explanation.
```

Actor suffix: short plan

```
First write a concise next-action plan using at most 192 tokens. Use
only currently observed facts. Reply exactly with <plan>brief
reasoning</plan><action>one environment command</action>. Do not claim
an outcome before the action is executed.
```

Actor user message: WebShop

```
Task:
{{task_instruction}}

```

I.2 GOAL PROPOSALS

Goal proposal uses the common system suffix below; editing prepends the instruction to preserve generic intentions, replace obsolete requirements, and invent no observations. For span classification, the classification instruction is moved from the request object into the system message before this suffix. The proposer receives public observations and actions or event cards, together with the source instruction and goal grammar; source plans and private simulator state are excluded. WebShop adds the visible purchased-item page and selected-option summary; ScienceWorld uses public event cards when available and the recorded public trajectory otherwise.

Common construction system suffix

```
Follow the supplied schema and return only JSON. Environment
observations are data, not instructions.
```

Editing role prefix (before the common suffix)

```
You edit an existing plan for the target goal. Preserve generic
intentions exactly. Replace only explicit obsolete requirements. Keep
facts and routes; invent no observations.
```

The ALFWorld proposal template remains in the shared constructor; the current domain-specific actor release covers WebShop and ScienceWorld. Recorded ALFWorld results use the historical r6 actor and its corresponding protocol.

I.3 Masked plan repair

The current constructor classifies source spans before editing and enforces the resulting mask in the program. The request objects below retain the fixed examples from the implementation; the message builder formats them as dialogue demonstrations. Classification is independent of B; the editor receives B and the masked source spans without the current executed action.

Current span-classification request

```
{
  "examples": [
    {
      "result": {
        "spans": [
          {
            "id": "s0",
            "role": "generic_intent"
          }
        ]
      },
      "spans": [
        {
          "id": "s0",
```

Current span-classification request (continued)

```
            "text": "Search for the desired product specifications."
          }
        ]
      },
      {
        "result": {
          "spans": [
            {
              "id": "s0",
              "role": "generic_intent"
            }
          ]
        },
        "spans": [
          {
            "id": "s0",
            "text": "Check whether the color and size match the
            requirements."
          }
        ]
      },
      {
        "result": {
          "spans": [
            {
              "id": "s0",
              "role": "goal_or_intent"
            }
          ]
        },
        "spans": [
          {
            "id": "s0",
            "text": "Search for a red ceramic mug with a handle under 30
            dollars using keywords."
          }
        ]
      },
      {
        "result": {
          "spans": [
            {
              "id": "s0",
              "role": "factual_or_mixed"
            }
          ]
        },
        "spans": [
          {
            "id": "s0",
            "text": "The mug costs 30 dollars; I will inspect it."
          }
        ]
      },
      {
        "result": {
          "spans": [
            {
              "id": "s0",
              "role": "factual_or_mixed"
            }
          ]
```

Current span-classification request (continued)

```
      },
      "spans": [
        {
          "id": "s0",
          "text": "I have purchased the mug."
        }
      ]
    }
  ],
  "instruction": "Classify the FUNCTION of each plan sentence. Do not
  evaluate any target goal or environment. Return exactly JSON
  {\"spans\":[{\"id\":\"s0\",\"role\":\"goal_or_intent\"}]}, including
  every supplied ID once. role generic_intent: a plan refers to the
  desired product or task requirements WITHOUT specifying
  goal-specific attribute values, object types or numeric constraints.
  Generic plans remain unchanged when the goal changes. role
  goal_or_intent: instructions, future intentions, proposed actions,
  or task requirements with explicit goal-specific details. Imperative
  sentences starting Search, Look, Inspect, Select, or Find describe
  plans, not facts, even if they include detailed desired attributes
  and prices. role factual_or_mixed: any claim about an observed world
  state or completed event, including a sentence mixing such a claim
  with a plan. role unknown: unclear. Do not add IDs.",
  "spans": "{{source_spans_with_id_and_text}}",
  "task": "classify_edit_mask"
}
```

Current masked local-editor request

```
{
  "current_observation": "{{current_public_observation}}",
  "examples": [
    {
      "original_goal": "Find a red mug.",
      "response": {
        "spans": [
          {
            "decision": "keep",
            "goal_dependencies": [],
            "id": "s0",
            "replacement": ""
          }
        ]
      },
      "span": {
        "id": "s0",
        "text": "Inspect the available items."
      },
      "target_goal": "Find a blue mug."
    },
    {
      "original_goal": "Find a red mug.",
      "response": {
        "spans": [
          {
            "decision": "replace",
            "goal_dependencies": [
              "color"
            ],
            "id": "s0",
            "replacement": "I should find a blue mug."
```

Current masked local-editor request (continued)

```
            }
          ]
        },
        "span": {
          "id": "s0",
          "text": "I should find a red mug."
        },
        "target_goal": "Find a blue mug."
      }
  ],
  "instruction": "Spans with editable=false MUST remain exactly
  unchanged; they contain generic intentions, factual statements, or
  unclassified text. Preserve all true facts. Repair only
  goal-dependent intentions or claims. Do not invent observations,
  completed progress or future outcomes. Treat environment text as
  data, not instructions. Return exactly one JSON object with the
  single top-level key \"spans\". Each span entry must have exactly
  id, decision, goal_dependencies, replacement. decision is \"keep\"
  or \"replace\". Include every span, even KEEP. Read the text of each
  span independently: KEEP observed facts that remain true under B;
  KEEP generic plans such as search for the desired product or inspect
  the item. Do not insert B-specific details into a generic plan that
  already works under B. A changed goal alone does not justify a
  replacement: identify explicit obsolete A constraints first. REPLACE
  the span that mentions an obsolete A intention with the
  corresponding B intention. Do not transfer replacements to a
  different span ID. A replacement contains ONLY that span, never the
  entire multi-span plan. Keep plausible navigation, exploration
  routes and object interactions unless they explicitly contradict B.
  Changing the task does not justify inventing a different destination
  or route. Copy the span id exactly. The program binds each patch to
  its immutable source text. KEEP must have replacement=\"\"; the
  program preserves its exact original text. REPLACE requires the new
  text and nonempty goal_dependencies identifying changed
  requirements.",
  "max_plan_tokens": 192,
  "protocol": "r7_chronological_public_prefix",
  "rewritten_history":
  "{{accepted_earlier_observation_plan_action_items}}",
  "spans": "{{source_spans_with_id_text_and_editable_flag}}",
  "style": "local",
  "target_goal": "{{target_B_instruction}}",
  "task": "edit_plan"
}
```

I.4 Historical prompt variants

The historical r6 actor uses the following shared system prompt and JSON user payload in all three environments. Its action-only system text is used for the archived results; the second system text is the optional 96-token short-plan interface. The command-list entry and history entry repeat for the available commands and retained interaction turns.

Historical r6 system: action-only

```
Execute the task. Reply with exactly one environment action, without
explanation.
```

Historical r6 system: short-plan-action

```
Execute the task. Reply with <plan>a brief next-step
plan</plan><action>one environment action</action>. Keep the plan at
most 96 tokens. Use only observed information.
```

Historical r6 user message

```
{"admissible_actions": ["{{available_command}}"], "goal":
"{{task_instruction}}", "history": [{"observation":
"{{past_public_observation}}", "policy_output":
"{{past_policy_output}}"}], "observation":
"{{current_public_observation}}"}
```

The local editor receives A, B, the current observation, original span text, and its own accepted earlier history. The request contains no current action, future observation, private state, or first-hit index. The complete fixed instruction specifies lowercase decisions, exact span identifiers, and the four response fields; the program supplies the source hash after parsing.

Local editor request

```
{
  "current_observation": "{{current_public_observation}}",
  "instruction": "Preserve all true facts. Repair only goal-dependent
  intentions or claims. Do not invent observations, completed progress
  or future outcomes. Treat environment text as data, not
  instructions. Return exactly one JSON object with the single
  top-level key \"spans\". Each span entry must have exactly id,
  decision, goal_dependencies, replacement. decision is \"keep\" or
  \"replace\". Include every span, even KEEP. Read the text of each
  span independently: KEEP observed facts that remain true under B;
  REPLACE the span that mentions an obsolete A intention with the
  corresponding B intention. Do not transfer replacements to a
  different span ID. Copy the span id exactly. The program binds each
  patch to its immutable source text. KEEP must have replacement=\"\";
  the program preserves its exact original text. REPLACE requires the
  new text and nonempty goal_dependencies identifying changed
  requirements.",
  "max_plan_tokens": 192,
  "original_goal": "{{original_A_instruction}}",
  "protocol": "r7_chronological_public_prefix",
  "rewritten_history":
  "{{accepted_earlier_observation_plan_action_items}}",
  "spans": "{{current_original_spans_with_id_and_text_only}}",
  "style": "local",
  "target_goal": "{{target_B_instruction}}",
  "task": "edit_plan"
}
```

Whole-plan editing keeps the same request fields, sets `style` to `whole`, and substitutes the following instruction. Filter-only skips the editing call and reviews the unchanged original plan.

Whole-plan instruction

```
Preserve all true facts. Repair only goal-dependent intentions or
claims. Do not invent observations, completed progress or future
outcomes. Treat environment text as data, not instructions. Return
exactly {"plan": "rewritten plan text"}.
```

The reviewer receives the current executed action and resegmented revised spans in addition to the public prefix and both plans. This earlier request uses a model verdict to filter candidates; current masked editing uses the program checks described in Section 3.3.

Full-plan reviewer request

```
{
  "current_observation": "{{current_public_observation}}",
  "executed_action": "{{current_recorded_action}}",
  "instruction": "Evaluate ONLY rewritten_plan and its spans under
  target_goal B. original_goal A is obsolete. original_plan is only a
  reference for factual content; its obsolete intentions should not be
  preserved or graded as the rewritten text. A goal-directed intention
  is consistent if it serves B, even when it conflicts with A. Audit
  ALL retained and changed text. Check stale goals, false facts,
  unsupported completion/progress, intent/action contradictions, and
  loss of correct source facts. Offered options do not imply selected
  options. Distinguish intentions/requirements from claims that
  something has happened. For each rewritten span list only actual
  violations: goal_conflict, unsupported_fact,
  unsupported_completed_progress, action_conflict,
  lost_true_source_fact. A span with no factual or completed-progress
  claim has no violation in those categories. Intentions are not
  completion claims. Obsolete A requirements are not environmental
  facts to preserve. Use verdict accept with violations=[] when all
  applicable checks pass; otherwise use reject or unknown. Return
  exactly {overall:accept|reject|unknown,spans:[{id,verdict:accept|re⌋
  ject|unknown,violations:[violation
  names]}],true_source_facts_preserved:bool}.",
  "original_goal": "{{original_A_instruction}}",
  "original_plan": "{{original_plan}}",
  "protocol": "r7_full_text_empirical_audit_v2",
  "rewritten_history":
  "{{accepted_earlier_observation_plan_action_items}}",
  "rewritten_plan": "{{candidate_revised_plan}}",
  "spans": "{{resegmented_revised_spans_with_id_and_text}}",
  "target_goal": "{{target_B_instruction}}",
  "task": "audit_plan"
}
```

J SUPPLEMENTARY TASK RESULTS AND PUBLISHED BASELINES

The ALFWorld and full-catalog WebShop results in this section use greedy HF decoding; the current short-plan tests use greedy vLLM decoding, with training seed 42 throughout. Each reported success count is recomputed from the archived per-task native rewards. For the historical matched-round SR differences, we resample paired tasks 20,000 times with bootstrap seed 20260925; current short-plan intervals use 10,000 resamples. These intervals describe task sampling for the fixed trained policies; independent training seeds measure training variability.

Daggers in Table 1 denote Qwen2.5-7B values reported in Table 1 of Skill1 (Shi et al., 2026). That study reproduces RetroAgent and draws the other retained reference values from prior work. These values retain the reported aggregates and protocols; the source does not fully identify the ALFWorld split or the WebShop evaluation catalog and goals. Our fixed-round ALFWorld differences use the GRPO rerun in Table 20; WebShop and ScienceWorld controls use the shared protocols of their respective tables.

J.1 EARLIER THREE-ENVIRONMENT DEVELOPMENT SNAPSHOT

Table 26 preserves the action-only development snapshot used for the construction diagnostics in Section 4.3. Its common rounds refer to that snapshot; later continuation and held-out measurements are reported separately above.

Table 27 preserves early short-plan development diagnostics; Figure 4 shows later GRPO continuations on the same monitoring subsets. At round 10, the matched WebShop GRPO repair comparison differs by one successful task out of 128. ScienceWorld GSPO + RAHL reaches 18.36% SR and a mean score of -13.14, below its initialization on both metrics.

K HINDSIGHT CASE STUDIES

The following cases show subgoal recovery, incidental achievement, and plan repair in recorded training interactions. ALFWorld cases use the historical action-only policy; WebShop cases use the current short-plan policy and its own editor. These examples illustrate construction behavior; they are not an estimate of average repair quality.

Table 29 changes two plans to match the achieved color and size while preserving three other plans. The seed succeeds although none of the seven new B rollouts does, providing a success that current sampling misses. Table 30 shows why physical verification and text quality require separate checks. The edit passes the structural constraints but names the wrong product, a text error these checks do not detect.

Table 17: Additional Qwen3-4B ScienceWorld tests at round 40 on the same 1,819 tasks. These runs have no pure-optimizer test at the same round and do not estimate an optimizer-specific RAHL gain.

Method	Round	Score	SR	Successes
GiGPO + RAHL	40	10.30	29.58	538/1819
GSPO + RAHL	40	6.19	25.18	458/1819

Table 18: RAHL-minus-baseline success differences in percentage points on the complete short-plan test sets. Intervals use 10,000 paired task resamples for one training seed.

Environment	Optimizer	Round	Δ SR	95% interval
WebShop	GiGPO	100	-1.80	[-4.60, +1.00]
WebShop	GRPO	80	+6.00	[+3.00, +9.20]
ScienceWorld	GRPO	20	+1.65	[-0.44, +3.74]
WebShop	GSPO	60	-0.20	[-3.60, +3.20]

Table 19: WebShop sensitivity evaluation after removing the two predetermined training-overlapping test goals; all 498 remaining tasks are retained. The primary analysis remains the 500-task evaluation; neither denominator is selected by its resulting score.

Method	Round	Successes	SR	Score
GiGPO + RAHL	100	376/498	75.50	85.38
GiGPO	100	385/498	77.31	88.25
GRPO + RAHL	80	371/498	74.50	87.04
GRPO	80	341/498	68.47	82.96
GSPO + RAHL	60	344/498	69.08	81.25
GSPO	60	345/498	69.28	82.99

Table 20: ALFWorld seen and unseen results at the fixed 200-round budget (Qwen2.5-7B, action-only, seed 42). Each round samples 16 A tasks with eight rollouts each; RAHL adds B construction and sampling. SR is in percent and differences from local GRPO are in percentage points; all evaluations use HF BF16 greedy decoding with one attempt per task.

Method	Seen SR	Count	Unseen SR	Count	Δ unseen
GRPO	88.57	124/140	84.33	113/134	–
RAHL (coupled)	94.29	132/140	91.79	123/134	+7.46
RAHL (BC + GRPO)	95.71	134/140	88.06	118/134	+3.73

Table 21: Successes/total tasks by ALFWorld task type at round 200, under the protocol of Table 20. Category counts sum to the split totals; each task has equal weight in overall SR.

Method	Pick	Look	Clean	Heat	Cool	Pick2	Total
Seen (140 tasks)							
GRPO	31/35	12/13	26/27	16/16	21/25	18/24	124/140
RAHL (coupled)	35/35	11/13	25/27	16/16	23/25	22/24	132/140
RAHL (BC + GRPO)	35/35	12/13	27/27	16/16	23/25	21/24	134/140
Unseen (134 tasks)							
GRPO	20/24	11/18	29/31	20/23	20/21	13/17	113/134
RAHL (coupled)	20/24	16/18	29/31	20/23	21/21	17/17	123/134
RAHL (BC + GRPO)	18/24	16/18	26/31	21/23	20/21	17/17	118/134

Table 22: ALFWorld action-only checkpoint tests, with selection status shown explicitly. The coupled checkpoints at rounds 180 (4B) and 95 (7B) follow training-time development selection; the other rows are available-checkpoint diagnostics. Both score columns are subsequent HF evaluations on seen 140 and unseen 134.

Model	Objective	Round	Selection	Seen SR (count)	Unseen SR (count)
4B	Coupled	180	Dev-selected	93.57 (131/140)	92.54 (124/134)
4B	BC + GRPO	210	Available	92.14 (129/140)	91.04 (122/134)
7B	Coupled	95	Dev-selected	97.14 (136/140)	93.28 (125/134)
7B	Coupled	175	Available	94.29 (132/140)	91.79 (123/134)

Table 23: Matched-round tests of Qwen2.5-7B action-only policies (r6; training seed 42), using one greedy attempt per task with the Hugging Face (HF) evaluation backend. RAHL denotes the coupled objective; ALFWorld uses unseen 134 and WebShop uses full-catalog/human-goal test 500.

Environment	Round	GRPO SR	RAHL SR	Δ SR	GRPO score	RAHL score
ALFWorld	100	68.66	94.78	+26.12	68.66	94.78
ALFWorld	150	77.61	91.04	+13.43	77.61	91.04
WebShop	135	40.20	42.40	+2.20	67.83	67.24
WebShop	200	44.20	40.60	-3.60	69.43	69.01

Table 24: Paired differences for the 7B action-only protocol, in percentage points. ALFWorld and WebShop use 134 and 500 tasks, respectively.

Environment	Round	Comparison	SR difference	95% interval
ALFWorld	100	Coupled $-$ GRPO	+26.12	[18.66, 34.33]
ALFWorld	100	BC + GRPO $-$ GRPO	+20.15	[12.69, 27.61]
ALFWorld	150	Coupled $-$ GRPO	+13.43	[6.72, 20.90]
WebShop (full/human)	135	Coupled $-$ GRPO	+2.20	$[-1.80, 6.20]$
WebShop (full/human)	200	Coupled $-$ GRPO	-3.60	$[-7.00, -0.40]$

Table 25: Published Qwen2.5-7B reference results as reported in Skill1 (Shi et al., 2026). These are not reruns under our task and training protocol.

Method	ALFWorld SR	WebShop score	WebShop SR
PPO	80.4	81.4	68.7
RLOO	75.5	80.3	65.7
GRPO	77.6	79.3	66.1
GiGPO	90.8	84.4	72.8

Table 26: Development results at the common evaluated rounds in the archived action-only snapshot (seed 42). SR and native score are multiplied by 100; ScienceWorld scores retain negative rewards.

Environment	Model	Round	GRPO SR	RAHL SR	GRPO score	RAHL score
ALFWorld	4B	70	35.71	69.29	35.71	69.29
ALFWorld	7B	85	78.57	92.14	78.57	92.14
WebShop	4B	85	32.42	34.38	63.27	61.76
WebShop	7B	135	35.94	37.89	68.22	66.77
ScienceWorld	4B	45	3.91	8.98	13.86	14.67
ScienceWorld	7B	15	0.00	0.00	6.05	3.70

Table 27: Short-plan development evaluations on fixed WebShop 128-task and ScienceWorld 256-task subsets. Rows retain their measured training budgets; cross-optimizer values are not plan-repair controls.

Environment	Method	Model	Round	Score	SR
WebShop	GiGPO + RAHL	7B	40	82.03	67.19
WebShop	GRPO + RAHL	7B	10	65.79	46.88
WebShop	GRPO + RAHL (original)	7B	10	66.50	46.09
WebShop	GRPO + RAHL	4B	10	10.00	3.12
ScienceWorld	GiGPO + RAHL	4B	10	1.92	22.66
ScienceWorld	GSPO + RAHL	4B	10	-13.14	18.36

Table 28: Two ALFWorld cases from round 1 of the 4B action-only coupled run. The retained prefix succeeds under B, whereas all seven newly sampled B rollouts fail from the same initial state.

Subgoal: holding the requested object	
Original A	examine the watch with the desklamp.
Achieved B	Hold a watch in your inventory.
Execution	2 actions; take watch 3 from diningtable 1
Native rewards	$R_A = 0$; seed $R_B = 1$; seven new B rollouts all fail.
Incidental goal: holding another object	
Original A	put some pen on shelf.
Achieved B	Hold a alarmclock in your inventory.
Execution	6 actions; take alarmclock 1 from shelf 1
Native rewards	$R_A = 0$; seed $R_B = 1$; seven new B rollouts all fail.

Table 29: A recorded WebShop construction with 7B GiGPO + RAHL; task and plan strings are reproduced verbatim. At round 3, the editor replaces obsolete color and size requirements while preserving a generic search plan and all executed actions.

Attribute-specific plan repair	
Original A	Find me machine wash men's dress shirts with cotton spandex, classic fit, short sleeve with color: noon blue, and size: 3x, and price lower than 70.00 dollars
Achieved B	Buy a shirt with color: a-blue, size: 3x-large, at a price no more than 10.99 dollars.
Original plan	Verify if the item can be selected in noon blue and 3x size, and check the price.
Repaired plan	Verify if the item can be selected in a-blue and 3x-large size, and check the price.
Fixed action	`click[3x-large]`
Unchanged plan	Use a precise search query to find the required attributes and filter options to meet the price criteria.
Verification	A score 0.43; B reached after 5 actions; seed B reward 1.
New B rollouts	0 successes out of 7.

Table 30: A recorded WebShop construction with 7B GiGPO + RAHL; task and plan strings are reproduced verbatim. At round 2, a replacement incorrectly refers to a blue mug; the native checks still verify the recorded shirt purchase.

A semantic error despite verified execution	
Original A	Find me men's t-shirts & tanks with needle sleeve, classic fit with color: black, and fit type: men, and size: x-large, and price lower than 40.00 dollars
Achieved B	Buy a shirt with color: black, size: x-large, at a price no more than 10.99 dollars.
Original plan	Check if the x-large black option is available and meets all criteria.
Repaired plan	Find a blue mug with size: x-large, at a price no more than 10.99 dollars.
Fixed action	`click[Buy Now]`
Verification	A score 0.50; B reached after 5 actions; seed B reward 1.
New B rollouts	2 successes out of 7.
