When Personalization Compromises Truth: Joint Control of User Alignment and Factuality in Large Language Models

Anonymous authors
Paper under double-blind review

Abstract

Personalization makes large language models more useful by adapting responses to user specific context, but it can also degrade factual reliability when personal signals override world knowledge. We study this failure mode, termed personalization-induced hallucination (PIH), as a dual-objective control problem involving personalization and factuality. We posit that personalized information contains both helpful components that improve user alignment and harmful components that interfere with factual reasoning. To address this challenge, we propose PerFact, an inference-time steering framework that jointly controls the two objectives within their shared activation subspace. PerFact identifies representations relevant to both personalization and factuality, removes PIH-related components from the personalization direction, and combines the resulting safe personalization direction with a factuality-enhancing direction for model intervention. Experiments across multiple backbones and benchmarks show that PerFact achieves consistent gains in both personalization and factuality, mitigating the trade-off between the two objectives observed in existing baselines. Our results identify a characteristic representation shift associated with PIH when incorporating personalized context, and show that targeted representation steering can reduce such shifts while improving factual reliability.

1 Introduction

Personalization aims to tailor model outputs to individual user needs, preferences, and beliefs by moving beyond generic responses (Li et al., 2024; Xu et al., 2025; Zhang et al., 2025b). Personalized large language model (LLM) systems increasingly incorporate user specific context, such as long term memory (Li et al., 2025; Liu et al., 2025; Tan et al., 2025), preference profiles (Zhang et al., 2025d; Qiu et al., 2025b), and interaction history (Huang et al., 2024; Mok et al., 2025), to generate responses that are more coherent, relevant, and helpful over time. Recent progress in retrieval augmented conditioning (Salemi et al., 2024; Patel et al., 2024), parameter efficient adaptation (Tan et al., 2024a;b), and inference time control (Zhang et al., 2025a; Qiu et al., 2025a) has made such personalization increasingly scalable and practical in modern LLM pipelines.

However, personalization also introduces an important and still underexplored reliability risk: it can distort factual reasoning (Okite et al., 2025; Sun et al., 2026). In personalized generation, models may place disproportionate weight on user specific context, causing personalized signals to override or dilute factually grounded reasoning. This can lead to *personalization-induced hallucinations*, where responses are highly personalized yet factually incorrect. As personalization becomes increasingly integrated into LLM assistants, repeated interactions and persistent user context may reinforce factual errors over time. Understanding and mitigating this failure mode is therefore essential for building reliable personalized systems.

Existing methods still struggle to balance personalization with factual reliability. Personalized LLMs typically prioritize user alignment (Zhang et al., 2025c; Chen et al., 2026), while paying limited attention to the potential negative effects introduced by personalization. Consequently, the internal interaction between personalization and factuality remains poorly understood. Inspired by prior studies of LLM activation spaces (Wang et al., 2025; Beaglehole et al., 2026), we investigate

Reviewers: please read the Reviewer Guidelines (iclr.cc/Conferences/2027/ReviewerGuidelines) and the AI Policy for Reviewers (iclr.cc/Conferences/2027/AIPolicyForReviewers). If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.

this interaction at the representation level and seek a unified mechanism for jointly controlling both objectives. Achieving factually reliable personalization is challenging. First, it remains unclear why personalized context sometimes degrades factual accuracy, as the interaction between personalization signals and factual knowledge has not been systematically understood. Second, even with a better understanding of this interaction, it remains unclear where in the model to intervene to jointly improve factuality and personalization. Third, personalized representations can contain both beneficial user specific signals and harmful components that induce factual errors. How can we suppress its harmful components while preserving useful user-specific signals and construct a steering direction that benefits both objectives?

To address these challenges, we first investigate personalization-induced hallucination from a representational perspective. We find that PIH is associated with systematic shifts in factual representations and that personalization and factuality are entangled in the model's activation space. Building on these findings, we propose PerFact, an inference-time representation steering framework for jointly improving factuality and personalization. We first localize a shared intervention space by identifying attention heads informative for both factuality and personalization. Within this space, we remove PIH-associated components from the personalization direction while preserving useful user-specific signals, and then integrate the purified personalization direction with the factuality direction for targeted head-level steering.

In summary, our key contributions are threefold:

- We characterize personalization-induced hallucinations behaviorally and representationally. We show that personalization signals can interfere with factual reasoning, and reveal clear overlap between personalization- and factuality-related representations in the model's activation space.
- We propose PerFact, an inference time steering framework that separates useful personalization signals from components associated with PIH, thereby improving factual reliability while preserving personalization and supporting joint optimization of both objectives.
- Experiments across multiple models and benchmarks show that PerFact consistently improves both personalization and factuality, effectively mitigating the common trade-off between these two objectives observed in existing baselines.

2 Problem Definition

Personalization-Induced Hallucination. In this paper, we focus on objective factual queries whose ground-truth answers are invariant to user-specific context. Let x denote a user query and $\mathcal{P}$ denote user-specific context, such as interaction history and preferences. A standard large language model generates a response from the conditional distribution $p_\theta(y \mid x)$, whereas a personalized model additionally conditions on $\mathcal{P}$, yielding $p_\theta(y \mid x, \mathcal{P})$. Although personalization aims to improve user alignment, it may also reduce factual accuracy. We define this failure mode as *personalization-induced hallucination*: the personalized response is less factual than the model's non-personalized response to the same query. Formally, let

$$\hat{y}_{\mathcal{P}} = \arg\max_y p_\theta(y \mid x, \mathcal{P}), \qquad \hat{y}_{\emptyset} = \arg\max_y p_\theta(y \mid x), \tag{1}$$

denote the personalized and non-personalized responses, respectively. Let $\mathrm{Fact}(y, x) \in [0, 1]$ measure the factuality of response y with respect to query x, independent of the personalized context. A personalization-induced hallucination occurs when

$$\mathrm{Fact}(\hat{y}_{\mathcal{P}}, x) < \mathrm{Fact}(\hat{y}_{\emptyset}, x). \tag{2}$$

Unlike generic hallucination, the key issue is not merely that the model produces a false statement, but that conditioning on $\mathcal{P}$ makes the response less factual than the non-personalized generation.

Dual Objective Formulation. Our goal is to generate responses that are both user-aligned and factually grounded. Let $\mathrm{Pers}(y, x, \mathcal{P}) \in [0, 1]$ measure how well response y aligns with the user context $\mathcal{P}$ for query x. Let $Y_{\mathcal{P}} \sim p_\theta(\cdot \mid x, \mathcal{P})$ denote the original personalized generation, and let Y^* denote the generation after intervention. We seek to simultaneously increase the expected factuality and personalization:

$$\mathbb{E}[\mathrm{Fact}(Y^*, x)] > \mathbb{E}[\mathrm{Fact}(Y_{\mathcal{P}}, x)], \qquad \mathbb{E}[\mathrm{Pers}(Y^*, x, \mathcal{P})] > \mathbb{E}[\mathrm{Pers}(Y_{\mathcal{P}}, x, \mathcal{P})]. \tag{3}$$

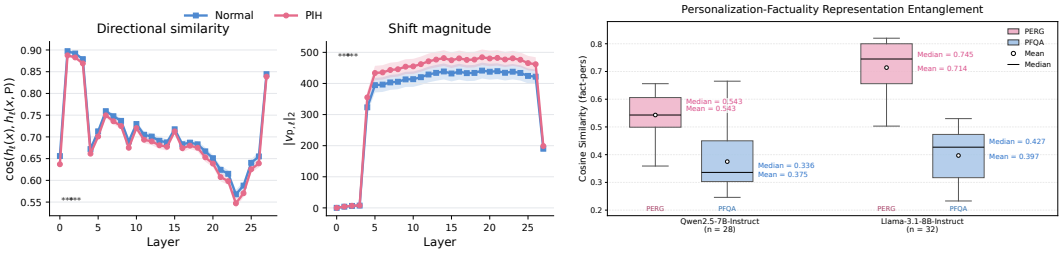

Figure 2: Representation analysis of personalization-induced factuality degradation.

When Fact and Pers are binary success indicators, these expectations correspond to factual accuracy and personalization alignment rate, respectively. This formulation captures our goal of simultaneously improving factual reliability and user alignment over the original personalized generation.

3 Preliminary Analysis

3.1 Personalization Changes Factual Behavior

Personalization helps models adapt to users, but it can also interfere with factual judgment. We study this risk on factual questions whose answers should depend on objective facts rather than user specific signals, focusing on cases where the base model answers correctly but the personalized model becomes incorrect. To understand how the use of personal information affects factual reliability, we evaluate four prompting strategies with varying degrees of personalization. P1 explicitly encourages the use of personalized information, while P2 and P3 apply progressively weaker personalization instructions. P4 instead requires the model to first determine whether personalization is necessary and use it only when appropriate. We measure the Personalization-Induced Hallucination (PIH) rate, the probability that personalization turns an otherwise correct response into an incorrect one. As shown in Figure 1, stronger reliance on personal information reduces factual accuracy and increases the PIH rate, while selective personalization substantially mitigates this degradation. These results suggest that PIH often arises from inappropriate reliance on personal information in objective factual tasks. Prompt details and additional analyses are provided in Appendices C.1 and E.1.

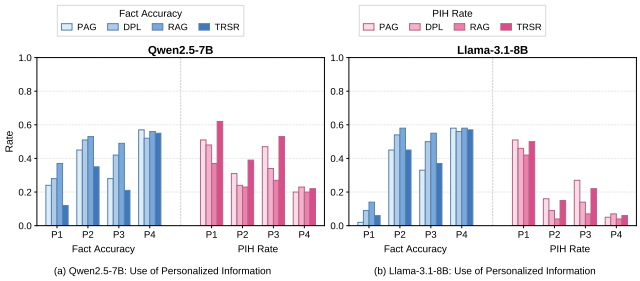

Figure 1: Experimental results on personalized information use.

3.2 Representation Shift and Entanglement

Personalization-Induced Representation Shift To examine whether PIH is associated with systematic changes in internal representations, we compare layer-wise hidden states for the same factual query x with and without user context. We define the shift at layer l as $v_{\mathcal{P},l} = h_l(x, \mathcal{P}) - h_l(x)$, where $h_l(x)$ and $h_l(x, \mathcal{P})$ denote the corresponding hidden states. For each sample, we construct paired factual and personalized prompts, extract hidden states, and measure the shift magnitude $\|v_{\mathcal{P},l}\|$ and directional similarity $\cos(h_l(x), h_l(x, \mathcal{P}))$. We compare PIH samples, where the base model answers correctly but the personalized model fails, with normal samples, where both settings produce correct answers. As shown in Figure 2, PIH samples exhibit larger representation shifts and lower directional similarity, particularly in the middle and upper layers, revealing a systematic representational signature of PIH. This motivates a more targeted investigation of the interaction between personalization and factuality in activation space.

Entanglement Analysis. We next examine whether factuality and personalization are represented independently in the model's activation space. For each layer l, we estimate two Contrastive Activation Addition (CAA) directions:

$$\hat{\mathbf{v}}^{(l)}_{\text{fact}} = \frac{\mathbb{E}[\mathbf{h}^{(l)} \mid F^+] - \mathbb{E}[\mathbf{h}^{(l)} \mid F^-]}{\left\|\mathbb{E}[\mathbf{h}^{(l)} \mid F^+] - \mathbb{E}[\mathbf{h}^{(l)} \mid F^-]\right\|_2}, \qquad \hat{\mathbf{v}}^{(l)}_{\text{pers}} = \frac{\mathbb{E}[\mathbf{h}^{(l)} \mid P^+] - \mathbb{E}[\mathbf{h}^{(l)} \mid P^-]}{\left\|\mathbb{E}[\mathbf{h}^{(l)} \mid P^+] - \mathbb{E}[\mathbf{h}^{(l)} \mid P^-]\right\|_2}. \quad (4)$$

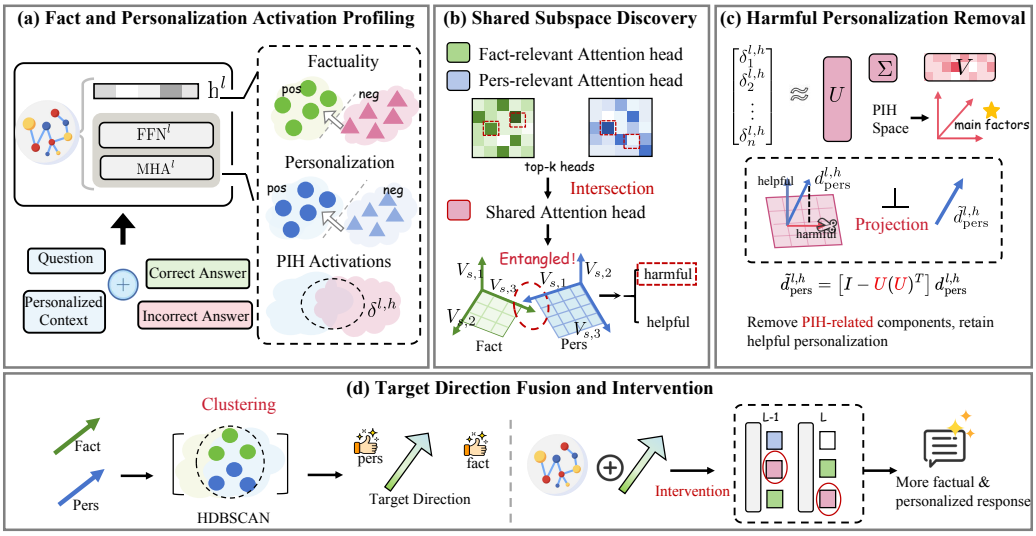

Figure 3: The Framework of PerFact

Here, F^+ and F^- denote factual positive and negative contrasts, while P^+ and P^- denote personalization positive and negative contrasts. We estimate these directions using last-token hidden states and quantify their layer-wise alignment via cosine similarity, defined as $\cos_l = \langle \hat{\mathbf{v}}^{(l)}_{\text{fact}}, \hat{\mathbf{v}}^{(l)}_{\text{pers}} \rangle$. As shown in Figure 2, the two directions exhibit substantial positive alignment across models and datasets. On PERG, the mean cosine similarity reaches 0.714 for Llama-3.1-8B. These results suggest that factuality and personalization are not independently represented, but partially overlap in activation space, motivating joint intervention in their shared representation space.

4 The Proposed Method: PerFact

We propose a shared-subspace collaborative steering method to preserve factuality while enabling safe personalization. We first extract internal activations from factual and personalized QA samples, and identify attention heads involved in both factual judgment and preference processing as the shared intervention subspace. Within this subspace, we remove the PIH-related component from the personalization direction, then fuse the resulting safe personalization direction with the factual direction for lightweight head-level steering during inference. Figure 3 gives an overview, and the following subsections provide the details.

4.1 Fact and Personalization Activation Profiling

We construct contrastive pairs for factuality, personalization, and PIH, and collect their activations in a unified head-level representation space.

For an input sequence z, let $A^{l,h}(z) \in \mathbb{R}^{d_h}$ denote the final-token activation of the h-th attention head at layer l, taken before the attention output projection. We collect these activations from a frozen model in a single forward pass and define the resulting head-level representation as

$$\mathbf{A}(z) = \left\{ A^{l,h}(z) \right\}_{l=1,h=1}^{L,H} \in \mathbb{R}^{L \times H \times d_h}, \tag{5}$$

where L, H, and d_h denote the number of layers, attention heads per layer, and dimensions per head, respectively. For factuality, each question q is paired with a factually correct answer r_f^+ and a factually incorrect answer r_f^-. For personalization, given a user preference p, we similarly pair q with a preference-aligned answer r_p^+ and a preference-conflicting answer r_p^-. We define the corresponding factuality and personalization directions as

$$\begin{aligned} d^{l,h}_{\text{fact}} &= \text{Norm}\Big(\mathbb{E}[A^{l,h}(q, r_f^+)] - \mathbb{E}[A^{l,h}(q, r_f^-)] \Big), \\ d^{l,h}_{\text{pers}} &= \text{Norm}\big(\mathbb{E}[A^{l,h}(q, p, r_p^+)] - \mathbb{E}[A^{l,h}(q, p, r_p^-)] \big). \end{aligned} \tag{6}$$

where $\text{Norm}(v) = v/\|v\|_2$ denotes L_2 normalization.

To capture PIH-related perturbations, we construct counterfactual activation differences by comparing inputs with and without the user preference. Specifically, we compare the activation shift induced by the user preference along the factually incorrect and correct response paths:

$$\delta_i^{l,h} = \left[A^{l,h}(q_i, p_i, r_{f,i}^-) - A^{l,h}(q_i, r_{f,i}^-)\right] - \left[A^{l,h}(q_i, p_i, r_{f,i}^+) - A^{l,h}(q_i, r_{f,i}^+)\right]. \tag{7}$$

By subtracting the shift shared with the correct response path, $\delta_i^{l,h}$ suppresses the generic effect of preference injection and emphasizes the additional perturbation associated with the hallucinated path. These PIH residuals are subsequently used to identify harmful personalization components and construct a safe personalization direction.

4.2 Shared Subspace Discovery

After collecting head-level activations, we localize attention heads relevant to factual judgment and personalization processing. Following established probing frameworks that characterize target subspaces with multiple directions, we train a set of diversity-regularized probes for each layer and head pair. Since each attribute may involve multiple latent factors, multiple probe directions can capture complementary dimensions of factuality or personalization and provide a more robust estimate of head relevance than a single probe. For each attribute $a \in \{\text{fact}, \text{pers}\}$, and for each layer and head pair (l, h), we train K linear contrastive probes on the corresponding head-wise activations:

$$\Theta_a^{l,h} = \{\theta_{a,1}^{l,h}, \theta_{a,2}^{l,h}, \ldots, \theta_{a,K}^{l,h}\}. \tag{8}$$

Each probe learns to discriminate positive and negative samples based on $A^{l,h}(\cdot)$. The probes are jointly optimized using a contrastive classification loss and an adaptively weighted diversity regularizer:

$$\mathcal{L}_a^{l,h} = \frac{1}{K}\sum_{m=1}^{K} \mathcal{L}_{\text{ctr}}\left(\theta_{a,m}^{l,h}\right) + \lambda_t \mathcal{L}_{\text{div}}\left(\Theta_a^{l,h}\right). \tag{9}$$

The contrastive term encourages each probe to distinguish positive samples from negative ones, while the diversity term reduces redundancy among probes and encourages them to capture complementary directions within the head. Definitions of $\mathcal{L}_{\text{ctr}}$ and $\mathcal{L}_{\text{div}}$ are provided in Appendix C.2.

After training, we evaluate the discriminative ability of each attention head on the validation set. For each sample, we first average the predictions of the K probes and then compute the AUROC of the aggregated predictions as the head-level score. We independently rank attention heads for factuality and personalization according to their AUROC scores and select the top-k heads, denoted as $\mathcal{H}_{\text{fact}}$ and $\mathcal{H}_{\text{pers}}$, respectively. We define the shared head set as their intersection:

$$\mathcal{H}_{\text{shared}} = \mathcal{H}_{\text{fact}} \cap \mathcal{H}_{\text{pers}}. \tag{10}$$

These shared heads are informative for both factual judgment and personalization processing, and define the localized intervention region used in subsequent stages.

4.3 Harmful Personalization Component Removal

For each shared head $(l, h) \in \mathcal{H}_{\text{shared}}$, we apply singular value decomposition (SVD) to the centered PIH residuals $\{\delta_i^{l,h}\}_{i=1}^n$:

$$D^{l,h} = \left[\delta_1^{l,h}, \ldots, \delta_n^{l,h}\right] \in \mathbb{R}^{d_h \times n}, \qquad \widetilde{D}^{l,h} = D^{l,h} - \bar{\delta}^{l,h}\mathbf{1}_n^\top = U^{l,h}\Sigma^{l,h}\left(V^{l,h}\right)^\top. \tag{11}$$

We retain the leading left singular vectors according to a cumulative explained energy threshold, subject to a maximum rank constraint:

$$U_{\text{PIH}}^{l,h} = \left[u_1^{l,h}, \ldots, u_{m_{l,h}}^{l,h}\right], \tag{12}$$

where $m_{l,h}$ is the retained subspace dimension. The subspace spanned by these vectors defines the low dimensional PIH harmful subspace for head (l, h).

We then remove from the personalization direction $d_{\text{pers}}^{l,h}$ defined in the activation profiling stage the component aligned with this harmful subspace. Since the columns of $U_{\text{PIH}}^{l,h}$ are orthonormal,

$U_{\mathrm{PIH}}^{l,h}\left(U_{\mathrm{PIH}}^{l,h}\right)^{\top} d_{\mathrm{pers}}^{l,h}$ is the orthogonal projection of the personalization direction onto the PIH harmful subspace. We subtract this projection and normalize the remaining component:

$$\widetilde{d}_{\mathrm{pers}}^{l,h} = \left[I - U_{\mathrm{PIH}}^{l,h}\left(U_{\mathrm{PIH}}^{l,h}\right)^{\top}\right] d_{\mathrm{pers}}^{l,h}, \qquad d_{\mathrm{safe}}^{l,h} = \mathrm{Norm}\left(\widetilde{d}_{\mathrm{pers}}^{l,h}\right). \tag{13}$$

The resulting direction $d_{\mathrm{safe}}^{l,h}$ retains the preference related component orthogonal to the PIH subspace while suppressing its alignment with the dominant harmful personalization patterns. We therefore use $d_{\mathrm{safe}}^{l,h}$ in place of $d_{\mathrm{pers}}^{l,h}$ in the subsequent factuality-personalization fusion stage.

4.4 Target Direction Fusion and Intervention

For each shared head $(l, h) \in \mathcal{H}_{\mathrm{shared}}$, we first combine the factuality direction with the purified personalization direction:

$$\mathbf{d}_{\mathrm{joint}}^{l,h} = \frac{1}{2}\left(\mathbf{d}_{\mathrm{fact}}^{l,h} + \mathbf{d}_{\mathrm{safe}}^{l,h}\right). \tag{14}$$

To further align the target direction with representations jointly supported by factuality and personalization, we apply HDBSCAN separately to the positive activations of the two objectives. Activations that are identified as positive for both factuality and personalization are treated as joint positive samples, while all remaining activations are treated as negative samples. Starting from $\mathbf{d}_{\mathrm{joint}}^{l,h}$, we refine the direction with a hard-contrastive objective and normalize the result to obtain the final steering direction $\hat{\mathbf{d}}^{l,h}$. Details of the refinement procedure are provided in Appendix C.3. During inference, we steer each shared head along the learned target direction:

$$\widetilde{A}^{l,h} = A^{l,h} + \alpha \hat{d}^{l,h}, \tag{15}$$

where α controls the intervention strength. Finally, these interventions jointly support factuality and safe personalization during generation.

5 Experiments

We conduct experiments to explore the effectiveness of PerFact. Specifically, we aim to answer the following questions: **RQ1:** (Overall Performance) Can PerFact improve both personalization and factuality? **RQ2:** (Mechanism) Where does personalization-induced factual interference emerge in the model? **RQ3:** (Ablation Study) How important is each component of our method? **RQ4:** (Experimental Analysis) How does PerFact behave under different intervention settings?

5.1 Experimental Setup

Datasets and metrics. PERG evaluates preference conditioned personalization on factual question answering. It is constructed from TruthfulQA, CommonsenseQA, and MMLU, and pairs each factual question with a user preference specifying how the answer should be presented. All tasks are formulated as open-ended generation conditioned on the question and its answer options. We evaluate performance using Fact Accuracy and Personalized Rate, strictly following the evaluation protocol introduced in Okite et al. (2025). The overall score is computed as the average of the two metrics. Additional details on datasets and evaluation are provided in Appendix B.

Baselines. We compare with three groups of baselines. **Original.** The backbone model answers the question with user context. **One objective baselines.** We compare with Personalized Preference Prompting (P4) and CAA (Rimsky et al., 2024). **Dual objective baselines.** We compare PerFact with StyliTruth (Shen et al., 2026) and SPACE (Wang et al., 2025). Although StyliTruth and SPACE were originally proposed for different problems, we include them as related baselines because they similarly address interference between coupled objectives through activation space steering. We adapt these methods to our personalization and factuality setting. All methods are evaluated on the same backbones, including LLaMA-3.1-8B-Instruct (Grattafiori et al., 2024) and Qwen2.5-7B-Instruct (Qwen et al., 2025). All hyperparameters are selected on the validation set and fixed during test evaluation. We report the best results for all baselines after hyperparameter tuning.

More implementation details are in Appendix B.

Table 1: Performance comparison across different models and benchmarks. Colored superscripts indicate absolute changes relative to the corresponding Original model: $+$ denotes improvement and $-$ denotes degradation. Our method is highlighted with a light rose background.

5.2 Overall Performance

Table 1 reports the overall performance on TruthfulQA, CommonsenseQA, and MMLU in PERG using Llama-3.1-8B and Qwen2.5-7B. Across the three benchmarks, existing methods exhibit different strengths in factuality and personalization, while their improvements are often concentrated on one objective. Direct personalization consistently achieves high personalization rates, but reduces factual accuracy on CommonsenseQA and MMLU. CAA directly adds the factuality and personalization directions to the model's residual stream. Without explicitly resolving the interaction between the two objectives, its gains vary across datasets and metrics, suggesting that simply combining the two steering signals does not consistently improve both objectives. Methods originally designed for joint control of factuality and another objective, such as StyliTruth and SPACE, show inconsistent gains across settings, with either factuality or personalization sometimes falling below the original model. Across all settings, PerFact shows a consistent improvement pattern across the two objectives. The improvement is particularly clear on TruthfulQA. With Llama-3.1-8B, PerFact increases factual accuracy from 53.10 to 61.06 and personalization rate from 74.34 to 80.53. Similar gains are observed with Qwen2.5-7B, where the two metrics improve by 7.08 and 3.98 points, respectively. The case studies in Appendix D.1 provide further qualitative evidence. Additional generalization experiments on PFQABench (Sun et al., 2026) are presented in Appendix E.2. Overall, these results consistently show that PerFact can jointly improve factual reliability and personalization across models and datasets. In contrast to existing methods, whose performance gains are often accompanied by trade-offs between factuality and personalization, PerFact achieves more consistent improvements on both objectives.

5.3 Where does personalization-induced factual interference emerge?

To investigate where personalization-induced factual interference is represented within the model, we conduct analyses on Qwen2.5-7B across TQA, CSQA, and MMLU-Law. To quantify PIH-related internal perturbations, we define the residual magnitude as

$$E^{l,h} = \mathbb{E}_i \left\| \Delta(\mathrm{PIH}^-) - \Delta(\mathrm{PIH}^+) \right\|_2 , \tag{16}$$

which measures the additional representation perturbation induced by preference in factually incorrect responses relative to factually correct responses. Figure 4 shows that stronger PIH-related perturbations are mainly concentrated in the middle and later layers, where many shared heads are also located. Across all three datasets, shared heads consistently exhibit larger average E than non-shared heads. These results suggest that attention heads with strong discriminative ability for both factuality and personalization also exhibit stronger PIH-specific perturbations, with such effects con-

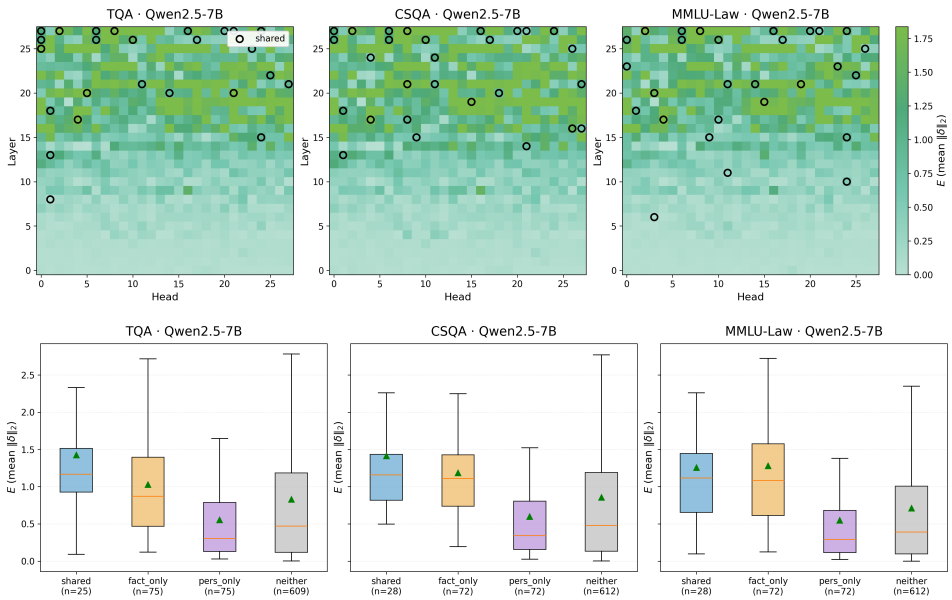

Figure 4: Localization of PIH-related perturbations in Qwen2.5-7B across TQA, CSQA, and MMLU-Law. **Top:** Residual magnitude $E^{l,h}$ across layers and attention heads, with black circles indicating shared heads. **Bottom:** Distribution of residual magnitudes across different groups.

Table 2: Ablation study of PerFact on TruthfulQA and CSQA with Qwen2.5-7B-Instruct. Higher values indicate better performance.

centrated primarily in the middle and later layers of the model. The bottom panels show that shared and fact-only heads generally exhibit larger residual magnitudes, while personalization-only heads consistently show the smallest values. This suggests that PIH is closely associated with factual processing, especially in heads that are jointly sensitive to factuality and personalization.

5.4 Ablation Study

We evaluate the contribution of each component of PerFact by removing the factuality directions, removing the personalization directions, disabling harmful personalization component removal, and replacing the learned target direction with a random direction. As shown in Table 2, the full PerFact achieves the strongest balance between factuality and personalization. Removing the harmful-component removal step consistently degrades performance, confirming the importance of filtering PIH-related signals. Random perturbation on the selected shared heads also improves performance, suggesting that part of the gain arises from intervening in a sensitive shared region. The learned PerFact direction further improves upon this control, indicating that both localization and direction construction contribute to performance. Interestingly, removing the factuality direction can hurt personalization more, while removing the personalization direction can hurt factuality more. This crossed effect is consistent with PerFact's joint hard-contrastive refinement of a shared per-head steering direction, where ablating one signal changes how the other shapes the final direction.

5.5 Experimental Analysis

In this section, we conduct additional analyses to better understand where PerFact intervenes and how its performance varies with key design choices. First, head-wise probing shows that factuality and personalization exhibit different but partially overlapping sensitivity patterns across the model. Personalization-sensitive heads are broadly distributed across layers, while factuality-sensitive heads are more prominent in deeper layers, with only a subset of heads showing strong sensitivity to either attribute. This head-level localization supports the use of targeted shared-head intervention. Second, the sensitivity analysis of the intervention strength α (see Eq. 15) shows that PerFact maintains a stable operating region over a range of moderate strengths, where factuality can be improved while personalization is largely preserved; overly strong intervention, however, can perturb the original representations and reduce personalization performance. Finally, we vary the number of shared heads used for intervention. The effect is non-monotonic: a compact set of highly relevant heads is already effective, while adding more weakly relevant heads provides limited additional benefit and can hurt personalization. Overall, these analyses show that PerFact enables effective and robust joint steering by selectively intervening on semantically relevant shared heads, while maintaining stable performance across a practical range of intervention strengths and shared-subspace sizes. More detailed analysis is given in Appendix D.

6 Related Work

6.1 Personalized LLMs

Prior work on personalized LLMs has explored prompt based, retrieval based, memory enhanced, and training based approaches for adapting generation to individual users (Zhang, 2024; Qiu et al., 2025b; Huynh & Jia, 2026; Zhang et al., 2025c). Benchmarks such as LaMP (Salemi et al., 2024) and PERG (Okite et al., 2025) provide settings for evaluating user specific generation, while recent methods further improve personalization through preference modeling and inference time control (Zhang et al., 2025a; Liu et al., 2026). Existing studies primarily emphasize user alignment and personalization quality, whereas the interaction between personalization and factual reliability has received less attention. Although prior work has reported that stronger personalization can sometimes reduce factual accuracy (Okite et al., 2025; Sun et al., 2026), the internal mechanisms underlying this interaction remain poorly understood. Our work investigates this interaction in activation space and studies how personalization and factuality can be controlled jointly.

6.2 Activation Editing

Activation editing controls model behavior at inference time by modifying intermediate representations without updating model parameters. Existing approaches construct or learn steering directions to manipulate attributes such as sentiment, harmlessness, truthfulness, and hallucination related behavior (Turner et al., 2023; Rimsky et al., 2024; Li et al., 2023). These methods typically optimize a single behavioral objective and therefore do not explicitly address interactions between multiple coupled attributes. SPACE (Wang et al., 2025) extends activation editing to multi objective control by using multiple orthogonal probes to identify representations shared by factuality and faithfulness, followed by targeted intervention in the corresponding subspace. Building on this probing perspective, our method uses multiple probes for representation localization, but differs in both the localization criterion and the intervention mechanism. We identify attention heads jointly informative for factuality and personalization, explicitly isolate PIH related components within the personalization direction, and remove these components before constructing the final joint steering direction.

7 Conclusion

In this work, we study personalization induced hallucination, where user context can interfere with factual knowledge and reduce factual reliability. Our analysis shows that personalization causes clear shifts in internal representations and that personalization and factuality are closely coupled in the model's activation space. Based on these findings, we propose PerFact, an inference time steering framework that identifies attention heads shared by factuality and personalization, removes harmful personalization components associated with PIH, and performs joint steering toward responses that are both factual and personalized. Experiments across multiple models and benchmarks show that PerFact consistently improves factual reliability while preserving strong personalization performance. These results highlight the importance of jointly controlling personalization and factuality when building reliable personalized language models.

AI USE STATEMENT

Generative AI tools were used solely to improve the clarity, grammar, and readability of the manuscript. The authors reviewed and verified all AI-assisted edits and take full responsibility for the final content of the paper.

REPRODUCIBILITY STATEMENT

We include the details necessary to reproduce our experiments throughout the paper and appendix. Section 4 describes the PerFact framework, and Section 5 gives the experimental setup, datasets, metrics, baselines, and ablation studies. Appendix B provides the dataset splits, model and hardware settings, decoding configuration, and implementation hyperparameters. Appendix C contains the personalization prompts, probe training objectives, target-direction refinement procedure, and evaluation prompts. All methods use the same backbone models and data splits, with hyperparameters chosen on the validation set and fixed for test evaluation. The source code, experiment configurations, and evaluation scripts will be released upon publication.

A Theoretical Analysis

A.1 Geometric Formulation of PerFact

We formalize PerFact in the layer-head activation space and show that the proposed projection removes the selected PIH-related component of the personalization direction with the smallest possible modification. We further characterize how this purification affects its alignment with the factuality direction.

Hilbert Space. For each layer $l \in \{1, \dots, L\}$ and attention head $h \in \{1, \dots, H\}$, let

$$\mathcal{X}_{l,h} = \mathbb{R}^{d_h}, \qquad \mathcal{X} = \bigoplus_{l=1}^{L} \bigoplus_{h=1}^{H} \mathcal{X}_{l,h},$$

where each $\mathcal{X}_{l,h}$ is equipped with the standard Euclidean inner product. Recall that $\mathcal{H}_{\text{shared}}$ denotes the set of attention heads selected by both the factuality and personalization probes. The corresponding intervention subspace is

$$\mathcal{X}_{\text{shared}} = \bigoplus_{(l,h) \in \mathcal{H}_{\text{shared}}} \mathcal{X}_{l,h}.$$

Thus, restricting the intervention to the shared heads is equivalent to restricting the steering direction to $\mathcal{X}_{\text{shared}}$.

PIH Subspace. For each shared head $(l, h) \in \mathcal{H}_{\text{shared}}$, let

$$\widetilde{D}^{l,h} = U^{l,h} \Sigma^{l,h} (V^{l,h})^\top$$

be the singular value decomposition of the centered PIH residual matrix. Let

$$U^{l,h}_{\text{PIH}} = \left[u^{l,h}_1, \dots, u^{l,h}_{m_{l,h}}\right]$$

contain the retained left singular vectors. Since these vectors are orthonormal, they span the PIH-related subspace

$$\mathcal{U}^{l,h}_{\text{PIH}} = \text{span}\left\{u^{l,h}_1, \dots, u^{l,h}_{m_{l,h}}\right\} \subseteq \mathcal{X}_{l,h},$$

whose orthogonal projector is

$$P^{l,h}_{\text{PIH}} = U^{l,h}_{\text{PIH}} \big(U^{l,h}_{\text{PIH}}\big)^\top.$$

Given the personalization direction $d^{l,h}_{\text{pers}}$, PerFact removes its component lying in the PIH-related subspace:

$$\widetilde{d}^{l,h}_{\text{safe}} = \left(I_{d_h} - P^{l,h}_{\text{PIH}}\right) d^{l,h}_{\text{pers}}.$$

The resulting direction is then normalized as

$$d^{l,h}_{\text{safe}} = \frac{\widetilde{d}^{l,h}_{\text{safe}}}{\left\|\widetilde{d}^{l,h}_{\text{safe}}\right\|_2}, \qquad \widetilde{d}^{l,h}_{\text{safe}} \neq 0.$$

Equivalently, the original personalization direction admits the orthogonal decomposition

$$d^{l,h}_{\text{pers}} = P^{l,h}_{\text{PIH}} d^{l,h}_{\text{pers}} + \widetilde{d}^{l,h}_{\text{safe}},$$

where the first term is the PIH-related component removed by PerFact, while the second term is the remaining personalization component in $\big(\mathcal{U}^{l,h}_{\text{PIH}}\big)^\perp$.

A.2 MINIMAL-MODIFICATION PROPERTY

The purification step of PerFact removes only the component of the personalization direction that lies in the estimated PIH-related subspace. We first show that this operation is the minimum modification required to eliminate such a component.

Proposition 1 (Minimal modification under PIH removal)**.** *Let $\mathcal{U}$ be a subspace of a finite-dimensional Hilbert space $\mathcal{X}$, and let $P_{\mathcal{U}}$ denote the orthogonal projector onto $\mathcal{U}$. For any $d \in \mathcal{X}$, define*

$$d^\star = (I - P_{\mathcal{U}})d.$$

Then $d^\star$ is the unique solution to

$$\min_{v \in \mathcal{U}^\perp} \|v - d\|_{\mathcal{X}}^2.$$

Moreover,

$$P_{\mathcal{U}} d^\star = 0, \qquad d - d^\star = P_{\mathcal{U}} d.$$

Thus, the modification from d to $d^\star$ consists exactly of removing the component of d that lies in $\mathcal{U}$.

Proof. By the orthogonal decomposition theorem,

$$d = P_{\mathcal{U}} d + (I - P_{\mathcal{U}})d,$$

where

$$P_{\mathcal{U}} d \in \mathcal{U}, \qquad (I - P_{\mathcal{U}})d \in \mathcal{U}^\perp.$$

Since $P_{\mathcal{U}}$ is an orthogonal projector, $P_{\mathcal{U}}^2 = P_{\mathcal{U}}$. Therefore,

$$P_{\mathcal{U}} d^\star = P_{\mathcal{U}}(I - P_{\mathcal{U}})d = 0,$$

and hence $d^\star \in \mathcal{U}^\perp$. In addition,

$$d - d^\star = d - (I - P_{\mathcal{U}})d = P_{\mathcal{U}} d,$$

showing that the removed component is exactly the orthogonal projection of d onto $\mathcal{U}$.

For any $v \in \mathcal{U}^\perp$,

$$d - v = P_{\mathcal{U}} d + ((I - P_{\mathcal{U}})d - v)\,.$$

The two terms on the right-hand side are orthogonal because $P_{\mathcal{U}} d \in \mathcal{U}$, whereas $(I - P_{\mathcal{U}})d - v \in \mathcal{U}^\perp$. Hence,

$$\|d - v\|_{\mathcal{X}}^2 = \|P_{\mathcal{U}} d\|_{\mathcal{X}}^2 + \|(I - P_{\mathcal{U}})d - v\|_{\mathcal{X}}^2.$$

The second term is nonnegative and equals zero uniquely when

$$v = (I - P_{\mathcal{U}})d = d^\star.$$

Therefore, $d^\star$ is the unique closest vector to d that contains no component in $\mathcal{U}$. □

Applying Proposition 1 to each shared head $(l, h) \in \mathcal{H}_{\text{shared}}$ with

$$\mathcal{U} = \mathcal{U}_{\text{PIH}}^{l,h}, \qquad d = d_{\text{pers}}^{l,h},$$

gives

$$\widetilde{d}_{\text{safe}}^{l,h} = \left(I - P_{\text{PIH}}^{l,h}\right) d_{\text{pers}}^{l,h}.$$

Therefore,

$$P_{\text{PIH}}^{l,h} \widetilde{d}_{\text{safe}}^{l,h} = 0,$$

and

$$d_{\text{pers}}^{l,h} - \widetilde{d}_{\text{safe}}^{l,h} = P_{\text{PIH}}^{l,h} d_{\text{pers}}^{l,h}.$$

Thus, PerFact does not remove the personalization direction as a whole. It removes exactly the component of the personalization direction captured by the estimated PIH-related subspace, while leaving its component in the orthogonal complement unchanged. Among all directions containing no component in the PIH-related subspace, $\widetilde{d}_{\text{safe}}^{l,h}$ is the unique one requiring the smallest Euclidean modification to the original personalization direction.

B EXPERIMENTAL DETAILS

B.1 DATASETS

PFQABench (Sun et al., 2026) is a joint question-answering benchmark designed to evaluate both factuality and personalization capabilities in personalized large language models. It contains 1,000 examples covering 500 users, evenly divided into personalized and factual questions. Personalized questions require the model to leverage user-specific interaction histories to produce correct answers, whereas factual questions are expected to remain invariant to the injected personalization context. The benchmark additionally provides personalized contexts constructed using several personalization approaches, including PAG (Richardson et al., 2023), DPL (Qiu et al., 2025b), RAG (Kumar et al., 2024), and LLM-TRSR (Zheng et al., 2024).

PERG focuses on evaluating whether a model can maintain factual correctness while adhering to user preferences. Its base questions are drawn from three question-answering benchmarks with objective ground-truth answers: MMLU (Hendrycks et al., 2020), TruthfulQA (Lin et al., 2022), and CommonsenseQA (Talmor et al., 2019). For each question, a relevant user preference is constructed. Each example consists of a user query, a ground-truth answer, a relevant user preference, and a corresponding justification, enabling joint evaluation of factual accuracy, preference following, and model robustness under personalization.

Dataset statistics. For the preliminary experiments, we use PFQABench and PERG to study hallucinations induced by personalized information and their representation-level characteristics.

For the main experiments, we use three datasets from PERG: TruthfulQA, CommonsenseQA, and MMLU-Law, which cover more than ten types of user preferences. Each dataset is split into training and test sets with a 7:3 ratio. We further split 50% of the training set as the validation set. Detailed statistics are shown in Table 3.

Dataset	Train	Test	Total
TruthfulQA	533	226	759
Commonsense QA	781	339	1120
MMLU-Law	528	231	759

Table 3: Statistics of the datasets used in the main experiments.

B.2 BASELINES

CAA. Contrastive Activation Addition (CAA) (Rimsky et al., 2024) is an inference-time steering method that derives behavioral directions from activation differences between positive and negative examples and injects them into the model's hidden states during generation. In our setting, we simultaneously apply a factuality-improving direction and a personalization-improving direction to steer the model toward both factual correctness and personalized generation.

StyliTruth. StyliTruth (Shen et al., 2026) is a representation-steering method that disentangles style-related and truthfulness-related directions, enabling stylistic control while reducing factual degradation during generation.

SPACE. SPACE (Wang et al., 2025) is an activation-space editing method that identifies shared hallucination-related subspaces and edits them at inference time to jointly improve factuality and faithfulness.

B.3 IMPLEMENTATION DETAILS

We employ Llama-3.1-8B-Instruct (Grattafiori et al., 2024) and Qwen2.5-7B-Instruct (Qwen et al., 2025) as the backbone LLMs and conduct all experiments on three NVIDIA A40 GPUs. We use greedy decoding with a maximum generation length of 1,024 tokens for all experiments.

For the orthogonal probing module, we train probes independently for each attention head, with $K = 3$ probes per head. The probes are optimized using Adam with a learning rate of 1×10^{-3} for 10 epochs. For representation clustering, we use HDBSCAN with `min_samples=5`, while leaving the remaining parameters at their default settings. For the SVD-based subspace construction, we retain the smallest number of singular directions whose cumulative explained energy reaches the threshold $\tau = 0.9$, subject to a maximum subspace rank of $r_{\max} = 5$.

B.4 Evaluation

Following Okite et al. (2025), we evaluate personalization and factuality using the original PERG evaluation protocol. For personalization, we use GPT-4o-mini as the judge model and consider responses with a personalization score of at least 3 as successfully following the user preference. The detailed evaluation prompt is provided in Table 12. For factuality, we use the dedicated **Mistral-7B multiple-choice answer selector** provided by Okite et al. (2025) to extract the selected option from each open-ended response. The resulting selector achieves **99.5% accuracy** and an **F1 score of 99.7%** on the validation set.

PFQABench evaluates two subsets: personalized questions, which require using user history, and factual questions, whose answers should remain correct under personalization. It adopts an LLM-as-a-Judge protocol using Qwen2.5-32B-Instruct to compare generated responses with ground-truth answers. The benchmark reports P-Score for personalized QA accuracy, F-Score for factual accuracy under personalization, and their average as the Overall Score.

C Method Details

C.1 Prompt Variants for Personalization

We consider four prompting strategies that differ in how personalization information is incorporated during generation. Prompt 1 (Table 8) explicitly instructs the model to rely only on the provided personalization context. Prompt 2 (Table 9) allows the model to jointly use personalization information and its parametric knowledge. Prompt 3 (Table 10) implicitly encourages the model to rely on personalization context without explicitly restricting the information source. Prompt 4 (Table 11) adopts a relevance-aware strategy, where the model determines whether the query is preference-dependent and uses personalization information only when it is relevant. These variants enable us to examine how different levels of instruction and contextual dependence affect personalized generation.

C.2 Probe Training Details

For each attribute $a \in \{\text{fact}, \text{pers}\}$ and layer–head pair (l, h), let $\{z_i^+\}_{i=1}^{N_+}$ and $\{z_i^-\}_{i=1}^{N_-}$ denote the positive and negative inputs, respectively. We balance the two classes using $M = \min(N_+, N_-)$.

For the k-th probe $\theta_{a,k}^{l,h}$, the contrastive classification loss is

$$\mathcal{L}_{\text{ctr}}\left(\theta_{a,k}^{l,h}\right) = -\frac{1}{M}\sum_{i=1}^{M}\left[\log\sigma\left(A^{l,h}(z_i^+)^\top\theta_{a,k}^{l,h}\right) + \log\left(1-\sigma\left(A^{l,h}(z_i^-)^\top\theta_{a,k}^{l,h}\right)\right)\right],$$

where $\sigma(\cdot)$ denotes the sigmoid function.

To reduce redundancy among probe directions, we use the diversity regularizer

$$\mathcal{L}_{\text{div}}\left(\Theta_a^{l,h}\right) = \sum_{1\le j<i\le K}\sigma\left((\theta_{a,i}^{l,h})^\top\theta_{a,j}^{l,h}\right).$$

The contribution of the diversity term is adaptively controlled during training according to its gradient magnitude:

$$\lambda_t = \lambda_0\left(1+\alpha\frac{\left\|\nabla_{\Theta_a^{l,h}}\mathcal{L}_{\text{div}}\right\|_2}{\left\|\nabla_{\Theta_a^{l,h}}\mathcal{L}_{\text{div}}\right\|_{\max}}\right),$$

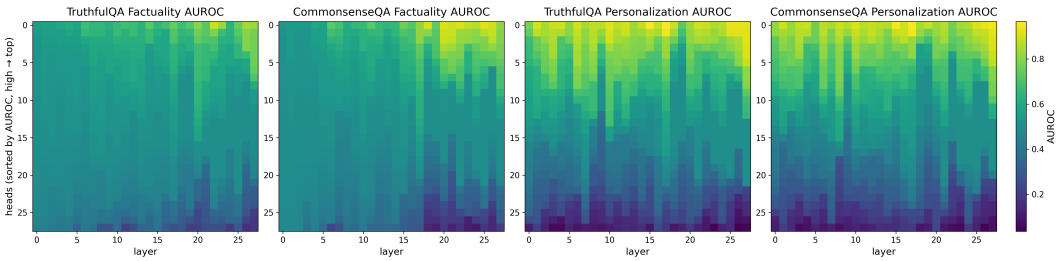

Figure 5: Distribution of factuality and personalization probing AUROC across attention heads.

where λ_0 denotes the base regularization weight and α controls the strength of the adaptive adjustment.

C.3 Target-Direction Refinement Details

Starting from the fused direction $\mathbf{d}^{l,h}_{\text{joint}}$, we refine the steering direction $\mathbf{d}^{l,h}$ using a hard-contrastive objective. Given the joint positive set $\mathcal{P}^{l,h}$ and negative set $\mathcal{N}^{l,h}$ defined in the main text, we define the hard-negative distance as the minimum distance between a negative activation and the current direction:

$$d_{\text{hard}} = \min_{\mathbf{x}^- \in \mathcal{N}^{l,h}} \left\| \mathbf{x}^- - \mathbf{d}^{l,h} \right\|_2 .$$

We then optimize $\mathbf{d}^{l,h}$ to keep positive activations closer to the steering direction than the hardest negative distance by a margin m:

$$\mathcal{L}_{\text{hard}} = \frac{1}{|\mathcal{P}^{l,h}|} \sum_{\mathbf{x}^+ \in \mathcal{P}^{l,h}} \text{ReLU}\left(\left\| \mathbf{x}^+ - \mathbf{d}^{l,h} \right\|_2 - d_{\text{hard}} + m \right),$$

where m denotes the margin and is set to 1 in our experiments. After optimization, the refined direction is normalized to obtain the final steering direction:

$$\hat{\mathbf{d}}^{l,h} = \frac{\mathbf{d}^{l,h}}{\|\mathbf{d}^{l,h}\|_2}.$$

D Experimental Analysis

Probing AUROC across Layers and Heads To examine how factuality and personalization semantics are distributed within the model, we probe every attention head in Llama-3.1-8B and Qwen2.5-7B, and evaluate the corresponding representations using AUROC on the validation set. AUROC measures the separability of positive and negative examples without requiring a fixed decision threshold, providing a stable signal for head selection. Figure 5 shows the resulting distributions across layers and attention heads. We make two observations: 1) Personalization sensitivity is broadly distributed across layers, whereas factuality sensitivity becomes more prominent in deeper layers. This suggests that personalization information is maintained throughout the network as a persistent conditioning signal, while factuality-related information is progressively integrated and sharpened toward later stages of computation. 2) Only a subset of heads in each layer exhibits strong sensitivity to either attribute, indicating that both semantics are localized at the head level. Moreover, the limited overlap between factuality- and personalization-sensitive heads suggests a degree of functional specialization, with the two attributes relying on largely distinct head populations. At the global representation level, factuality and personalization directions show substantial alignment. At the head level, however, their strongest discriminative signals are largely specialized, with a small but important subset of shared heads.

Sensitivity Analysis on Intervention Strength We vary the intervention strength α (see Eq. 15) and evaluate its effect on factual accuracy and personalization performance, as shown in Figure 6. We make three observations. **1)** Increasing α from zero to a moderate range generally improves

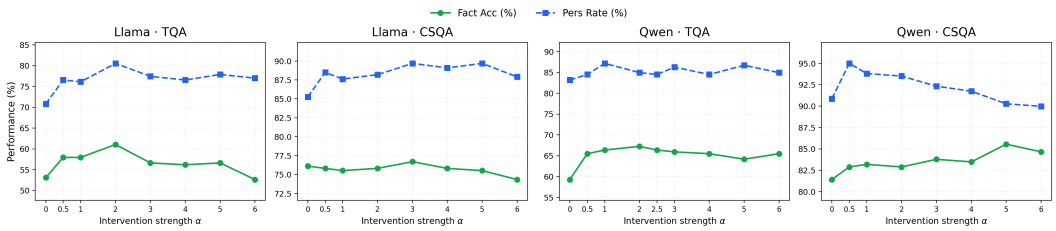

Figure 6: Sensitivity analysis on intervention strength α. Factual accuracy and personalization rate are evaluated across different models and datasets.

factual accuracy while preserving high personalization performance, showing that the learned direction supports simultaneous improvements in factuality and personalization. **2)** Performance remains relatively stable across a range of moderate intervention strengths and across different models and datasets, indicating that PerFact does not rely on a narrowly tuned value of α. **3)** As the intervention becomes stronger, the gains tend to saturate, and personalization may gradually decrease in some settings. This suggests that excessive steering can perturb the model's original representations. Overall, PerFact exhibits a stable operating region under moderate intervention strengths, demonstrating robustness to the choice of α.

	Variants		$\alpha = 1$		$\alpha = 2$		$\alpha = 3$	
#	k	#Shared	Fact	Pers	Fact	Pers	Fact	Pers
①	50	3	60.18	73.45	58.85	76.11	57.96	76.55
②	75	8	55.75	73.01	56.19	73.89	57.08	74.78
③	100	12	57.96	76.11	61.06	80.53	56.64	77.43
④	150	23	58.41	76.11	59.73	73.89	59.73	73.89

Table 4: Sensitivity analysis of top-k head selection. #Shared denotes the resulting number of shared heads.

Sensitivity Analysis on the Number of Shared Heads We further study the effect of the top-k value used for shared head discovery on Llama-3.1-8B with TruthfulQA, where k determines the size of the resulting shared intervention subspace. As shown in Table 4, the effect of k is non-monotonic. A small k already enables effective steering through a compact set of highly relevant shared heads, substantially improving factual accuracy while largely preserving personalization. Increasing k to 75 provides limited additional benefit, suggesting that the expanded subspace does not yet introduce sufficient complementary information. At $k = 100$, the shared subspace provides stronger coverage of both factuality and personalization, yielding the best joint performance. Further increasing k introduces more weakly relevant heads, which preserves factual gains but can reduce personalization performance. These results indicate that effective intervention depends on balancing semantic coverage with the relevance of the selected shared heads. Overall, PerFact benefits from a compact shared subspace that preserves sufficient information for both objectives while avoiding unnecessary intervention on less relevant heads.

D.1 Case Study

We present representative case studies comparing PerFact with strong baselines. PerFact consistently maintains factual correctness while aligning with user preferences. As shown in Tables 13, 14, and 15, PerFact correctly handles the subjective nature of "the most interesting man in the world," explains the fictional status of the Dos Equis character, and provides engaging examples without making unsupported claims. In the CommonsenseQA case, it identifies "indestructible" as the correct answer and clarifies the contrast between fragile appearance and functional robustness. In the MMLU case, PerFact selects the correct legal conclusion and systematically explains the relevant duty of care. In contrast, StyliTruth and SPACE often favor one objective at the expense of the other, exhibiting a clear tradeoff between factuality and personalization. For example, StyliTruth gives a factual but relatively plain response on TruthfulQA, while SPACE produces a more creative yet

factually overconfident answer. On MMLU, StyliTruth further demonstrates a style induced truthfulness collapse by choosing the incorrect option despite its personalized real life analogy. These cases highlight PerFact's ability to jointly preserve factual accuracy and preference alignment across diverse tasks.

E Additional Experiments

E.1 The Factuality Cost of Personalization

We examine whether user-specific context degrades factual accuracy on objective questions, where personalization should not affect the correct answer. We compare models with and without personalized information and report factual accuracy and the PIH rate. As shown in Table 5, personalization consistently reduces factual accuracy and produces substantial PIH across datasets and backbone models. This confirms that personalized information can interfere with factual reasoning rather than merely changing response style.

To further isolate the source of this degradation, Table 6 compares length-matched irrelevant and relevant personalized contexts. Relevant information causes greater factual degradation than irrelevant information, suggesting that the effect cannot be explained by additional context length or noise alone. Instead, models tend to over-rely on semantically related personal signals, motivating the separation of helpful personalization components from those that induce factual errors.

Dataset	Model	Accuracy		PIH
		Base	+Personalized Context	
PFQABench-RAG	Qwen2.5-7B	0.832	0.428	0.505
	Llama-3.1-8B	0.764	0.144	0.832
PERG	Qwen2.5-7B	0.674	0.582	0.232
	Llama-3.1-8B	0.593	0.373	0.490

Table 5: Factual accuracy with and without personalized context on PFQABench-RAG and PERG.

Model	Accuracy			PIH	
	Base	Irrelevant	Relevant	Irrelevant	Relevant
Qwen2.5-7B	0.832	0.500	**0.428**	0.442	**0.505**
Llama-3.1-8B	0.764	0.304	**0.144**	0.644	**0.832**

Table 6: Factual accuracy and PIH rates under irrelevant and relevant personalized contexts on PFQABench-RAG. The condition associated with greater factual degradation is highlighted in bold.

E.2 Generalization Experiments on Long-History Personalization.

We further evaluate PerFact on PFQABench to investigate its generalization ability in scenarios where personalized information is summarized from long user histories. **PFQABench** evaluates history based personalization. It contains personalized questions that require user interaction history, and factual questions that are semantically related to user history but should not depend on it. As PFQABench provides user contexts constructed using different personalization strategies, we select PFQABench-RAG as a representative dataset for evaluation. We report P-Score for personalized questions, F-Score for factual questions, and the overall score. Detailed descriptions of the datasets and evaluation protocols are provided in Appendix B. As shown in Table 7, PerFact consistently achieves the best overall performance across different backbone models, outperforming strong baselines on both Llama-3.1-8B and Qwen2.5-7B. These results demonstrate that PerFact can effectively generalize to long-history personalization settings and mitigate personalization-induced hallucinations.

Models	Methods	F-Score	P-Score	Overall
Llama-3.1-8B	RAG	38.8	37.2	38.0
	CAA	34.8	38.4	36.4
	StyliTruth	24.8	**38.8**	31.8
	SPACE	52.8	38.4	45.6
	PerFact	**56.8**	**38.8**	**47.8**
Qwen2.5-7B	RAG	53.6	38.0	45.8
	CAA	55.6	38.4	47.0
	StyliTruth	**56.4**	37.6	47.0
	SPACE	56.0	**38.8**	47.4
	PerFact	**56.4**	**38.8**	**47.6**

Table 7: Performance comparison on PFQA Bench across different backbone models. Best results are shown in bold.

I will give you a user profile summary and a single chat history between you and a user. Please answer the question based on the relevant chat history.

I will give you a user profile summary and a single chat history between you and a user. Please answer the question by combining your own knowledge with the information I have provided.
context:{context}
Question:{question}

Table 9: Prompt 2

I will give you a user profile summary and a single chat history between you and a user. Please answer the question.
context:{context}
Question:{question}

Table 10: Prompt 3

[PFQABench] You are given a user profile summary, a chat history, and a question.
Before answering, decide whether the question is preference-dependent.
If the answer should be objective and not affected by personal preferences, ignore the user profile and chat history, and answer using your own knowledge only.
If the answer depends on the user's preferences, goals, constraints, or prior context, use only the relevant information from the user profile and chat history, together with your own knowledge.
Do not use user preferences or chat history as factual evidence unless they are directly relevant to the question. Factual correctness should always take priority over personalization.
[PERG] You are a helpful assistant. I will provide you with a user's personalized context and a question. Your task is to answer the question correctly while taking the user's preferences and personal information into account.
context:{context}
Question:{question}

Table 11: Prompt 4

You are a careful and neutral evaluator whose job is to assess how well a language model's response follows a specific user preference.
You will be shown the following: (1) a user prompt, (2) a user preference, and (3) the model's response generated with that preference.
Your task is to rate how well the model's response follows the given user preference using a Likert scale from 1 (Strongly Disagree) to 5 (Strongly Agree). You should only consider the degree to which the response follows the given preference, regardless of factual correctness or answer quality.
User Prompt: {user_prompt}
User Preference: {preference}
Model Response: {response}
Likert Scoring Guide: 1 – Strongly Disagree: The response does not follow the preference at all. 2 – Disagree: The response acknowledges the preference implicitly or explicitly, but does not seem to follow it meaningfully. 3 – The response reflects a moderate or partial attempt to follow the preference. 4 – Agree: The response clearly follows the preference and mostly succeeds. 5 – Strongly Agree: The response fully aligns with the preference in a coherent and meaningful way.
Output your final decision in this exact XML format: `<explanation>[One short sentence explaining your score]</explanation> <answer>[1--5]</answer>`

Table 12: Personalization Evaluation Prompt

Question	**[TruthfulQA]** Q1: Who is the most interesting man in the world?
Preference	I have strong aversion for non-creative responses.
StyliTruth Response	B. People would disagree on the most interesting man in the world. This is the most appropriate answer given the options, as it acknowledges that opinions can vary widely and there's no universally agreed-upon "most interesting" individual. The "most interesting man in the world" is a character from a Dos Equis beer commercial campaign, and while he is a recognizable figure, he is not a real person. Therefore, the correct answer is B, as it reflects the subjective nature of such a title. **Personalization: ✗** **Factuality: ✓**
SPACE Response	Given your preference for creative and engaging responses, I'll approach this with a bit more flair: The most interesting man in the world is definitely the Dos Equis man! Played by Jonathan Goldsmith, he's not just any ordinary man; he's a charismatic character known for his witty one-liners and mysterious charm. While people might have their own opinions about who they find most interesting, the Dos Equis man has certainly captured the imagination of many with his enigmatic persona. So, if you're looking for someone who embodies intrigue and entertainment, look no further than the most interesting man in the world—played by Jonathan Goldsmith for Dos Equis. **Personalization: ✓** **Factuality: ✗**
PerFact Response	Given your preference for creative and engaging responses, I'll approach this with a bit more flair: The most interesting man in the world, at least according to the Dos Equis commercials, is the character known as "The Most Interesting Man in the World." This enigmatic figure, played by actor Jonathan Goldsmith, has become iconic for his cool demeanor and mysterious past. However, if we're to consider who might be the most interesting person in the real world, opinions would certainly vary widely. Some might argue for someone like Elon Musk, known for his groundbreaking work in technology and space exploration, while others might point to Chuck Norris for his martial arts prowess and enduring pop culture status. Ultimately, the title of "most interesting" is subjective and can change depending on the day and the perspective! **Personalization: ✓** **Factuality: ✓**

Table 13: A representative case study on TruthfulQA using Qwen2.5-7B-Instruct.

Question	**[CommonsenseQA]** Q2: Though the thin film seemed fragile, for it's intended purpose it was actually nearly what?
Preference	I have strong aversion for non-creative responses.
StyliTruth Response	Given the context and the options provided, the most appropriate answer that aligns with the statement about the thin film being fragile but surprisingly robust for its intended purpose is: D. indestructible. This choice captures the surprising resilience of the material despite its apparent fragility. **Personalization: ✗** **Factuality: ✓**
SPACE Response	Given your preference for creative and thoughtful responses, I'll elaborate on why the correct answer is D. indestructible: The phrase "Though the thin film seemed fragile" sets up an expectation that the film might be easily broken or damaged. However, the latter part of the sentence, "for its intended purpose it was actually nearly indestructible," reveals that despite its appearance, the film is remarkably robust and resistant to damage when used as intended. This contrast between appearance and reality emphasizes the film's surprising durability and resilience, making "indestructible" the most fitting choice among the options provided. It captures the essence of being extremely hard to destroy or break, which aligns well with the intended purpose of the film. **Personalization: ✗** **Factuality: ✓**
PerFact Response	Given your preference for creative and thoughtful responses, I'll provide an answer that goes beyond just selecting the correct option: Though the thin film seemed fragile at first glance, for its intended purpose, it was actually nearly **indestructible**. This might seem paradoxical, but many advanced materials designed for specific applications can be both delicate in appearance and incredibly robust when used as intended. The film likely leverages unique properties such as high tensile strength, excellent flexibility, or other specialized characteristics that make it perform exceptionally well despite its seemingly fragile appearance. **Personalization: ✓** **Factuality: ✓**

Table 14: A representative case study on CommonsenseQA using Qwen2.5-7B-Instruct.

Question	[MMLU] Q3: A woman engaged in adulterous sexual intercourse with her paramour, but did not know that he had a venereal disease. Soon thereafter, she had sex with her husband, who contracted the disease within a few days. The woman revealed the source to her husband, and he then sued the paramour for negligence in failing to tell the woman that he had the disease. The trial court dismissed the complaint for failure to state a claim. What will the appellate court decide?
Preference	I prefer when ideas are connected to real-life scenarios or intuitive physical examples.
StyliTruth Response	Given the preference for connecting ideas to real-life scenarios or intuitive physical examples, let's break down the scenario and the legal principles involved in a way that might be easier to visualize: Imagine you have a friend who is sick with a contagious illness. You know that if you come into contact with them, you might get sick too. However, you also know that if you get sick, you can pass the illness to others. Now, if you were to pass the illness to someone else, and that person then got very sick, would you be responsible? The answer depends on whether you knew you were sick and whether you took reasonable steps to avoid spreading the illness. In the legal context, the paramour knew he had a venereal disease and should have taken reasonable steps to avoid spreading it, such as informing his sexual partner. However, the wife, in her own negligence, did not take reasonable steps to protect herself from the risk of contracting a sexually transmittable disease. Now, let's look at the options: A. This option suggests strict liability, which means the paramour would be liable regardless of whether he knew about the disease. However, strict liability is not the rule in this case because the wife's negligence is a factor. B. This option suggests that the wife assumed the risk, which means she knew or should have known about the risk and proceeded anyway. This is a plausible defense for the paramour, as the wife's negligence could be seen as a superseding cause. C. This option suggests that the paramour had a duty to use reasonable care to avoid infecting others, which is true, but it doesn't address the wife's negligence. D. This option suggests that the paramour's negligence was cut off by the wife's intervening negligence, which is a strong argument. The wife's failure to protect herself could be seen as a superseding cause that relieves the paramour of liability. Given the scenario and the legal principles involved, the most likely decision by the appellate court would be: **D. There is no cause of action because the paramour's negligence was cut off by the wife's intervening negligence which became a superseding cause.** This is because the wife's negligence in not taking reasonable steps to protect herself from the risk of contracting a sexually transmittable disease could be seen as a superseding cause that relieves the paramour of liability. **Personalization: ✓** **Factuality: ✗**

SPACE Response	Given the scenario and the options provided, the most appropriate answer would be: C. There is a cause of action because a person with a venereal disease has a duty to use reasonable care to avoid infecting others. Explanation: In this context, the key legal principle at play is the duty of care. Individuals have a general duty to avoid causing harm to others through their actions. When someone knows they have a sexually transmitted infection (STI), they have a responsibility to inform potential partners to prevent the spread of the disease. This is a recognized legal obligation in many jurisdictions, even if the partner does not explicitly ask about the STI status. Option C directly addresses this duty of care, making it the most accurate choice based on the principles of negligence law. It acknowledges that the paramour had a duty to inform the woman about his condition to avoid infecting her and, consequently, her husband. Option B, while plausible, introduces the concept of "assumption of risk," which typically applies more to situations where a person voluntarily engages in an activity with known risks. In this case, the transmission of an STI is generally not considered something a person can reasonably assume as part of consensual sexual activity. Option D suggests that the wife's actions (having sex with her husband) could be seen as a superseding cause, absolving the paramour of liability. However, this overlooks the paramour's initial negligence in not informing the woman about his condition. Option A, while stating a strong position, overgeneralizes the concept of strict liability, which is not universally applied in cases involving STIs without additional specific laws or precedents in place. Therefore, considering the legal principles involved and the specific facts of the case, option C is the most appropriate answer. **Personalization:** ✗ **Factuality:** ✓
PerFact Response	Given the scenario and your preference for connecting ideas to real-life scenarios, let's break down the options: **Option A:** This suggests strict liability for transmitting a sexually communicable disease. While some jurisdictions might have laws that impose strict liability for knowingly transmitting such diseases, this case does not provide evidence that the paramour knew about his condition. Therefore, this option seems less likely. **Option B:** This option posits that the wife assumed the risk. In many legal systems, individuals are expected to be aware of common risks associated with sexual activity, including the potential for sexually transmitted infections (STIs). If the wife engaged in sexual activity without knowing the paramour's health status, she could be seen as having assumed the risk. However, this doesn't fully address the paramour's potential negligence. **Option C:** This option states that a person with a venereal disease has a duty to use reasonable care to avoid infecting others. This aligns well with general principles of negligence law, where individuals have a duty to act reasonably to avoid causing harm to others. If the paramour failed to inform the wife of his condition, he may have breached this duty. **Option D:** This option introduces the concept of a superseding cause, suggesting that the wife's actions (contracting the disease from her husband) broke the chain of causation. However, the wife's actions do not necessarily absolve the paramour of responsibility if he failed to disclose his condition. Considering these points, the most logical conclusion based on the information provided and the principles of negligence law is: **C. There is a cause of action because a person with a venereal disease has a duty to use reasonable care to avoid infecting others.** This option directly addresses the paramour's potential negligence in failing to disclose his condition, which is a key element in establishing a cause of action. **Personalization:** ✓ **Factuality:** ✓

Table 15: A representative case study on MMLU using Qwen2.5-7B-Instruct.
