WHAT DOES LLM-JUDGED NOVELTY REWARD? CONTROLLED EXPERIMENTS ON CONTEXT, WORKFLOW, AND MEASUREMENT VALIDITY

Anonymous authors
Paper under double-blind review

ABSTRACT

Large language model (LLM) research-ideation systems are increasingly evaluated with LLM judges of novelty, yet what those judgments reward is unclear. We vary paper contexts, generation instructions, and revision guidance while holding the research question and main rubric fixed. Judges see only the question and idea texts, in both display orders. The rubric rewards substantive departures from known work. An aligned generation instruction requiring a component beyond combining known methods increased preference across two generator families and two judge families. Giving this instruction only to GPT-5 mini reversed the preference for GPT-5. When the generator was asked to plan verification before revising a draft, the judge more often preferred the version revised without that instruction, even though the proposed verification was never carried out. Retrieving prior work and giving the generator feedback on possible overlap before each review round produced ideas the judge preferred to those from general review. To assess how these judgments relate to scientific novelty, we also examined consistency and agreement with existing expert ratings. Reversing display order changed the judge's preferred idea in nearly one fifth of pairs answered in both orders, and its choices only partly matched expert preferences. The judge's preference alone does not establish that the favored ideas make more original scientific contributions.

1 INTRODUCTION

Many research-idea systems use prompted LLM judges to assess novelty alongside, or instead of, expert review (Lu et al., 2024; Baek et al., 2025; Li et al., 2025; Hu et al., 2025; Su et al., 2025; Mo et al., 2026; Gottweis et al., 2026). These judgments increasingly determine which systems are reported as better, yet a preference gain need not establish greater scientific originality. We hold the question fixed and vary generation instructions, retrieved papers, and revision guidance. An instruction aligned with the judge's stated novelty criterion reversed preference for GPT-5 over GPT-5 mini when only mini received it. We distinguish instructions given during generation from explanations added to finished ideas and examine consistency and agreement with existing expert ratings (Figure 1).

1. **Instructions aligned with the rubric can reverse model rankings.** Asking for a nonstandard component directly targets the judge's criterion of a substantive departure from known work. It raised preference across two generator families and two judge families and reversed the GPT-5 versus GPT-5 mini comparison. In a follow-up, requesting a nonstandard component or an explanation during generation increased preference, whereas adding an explanation to an existing idea changed little (Section 4).
2. **Verification and prior work feedback shift judgments in opposite directions.** Asking the generator to plan verification lowered the judge's preference for the revised idea relative to general review, whereas retrieving prior work and flagging possible overlap with it raised it. The decrease held across three judge families (Section 5).
3. **Evidence for effects of retrieval content and model size is mixed.** Ideas generated with retrieved papers were preferred to those generated without papers. Neither relevance nor diversity

Reviewers: please read the Reviewer Guidelines (iclr.cc/Conferences/2027/ReviewerGuidelines) and the AI Policy for Reviewers (iclr.cc/Conferences/2027/AIPolicyForReviewers). If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.

changed preference detectably, and requiring the generator to build on the papers did not raise preference further. GPT-5 was preferred to GPT-5 mini, but no Qwen3 size comparison separated size from length (Section 6).

4. **The judge is order-sensitive and agrees only partly with experts.** Reversing display order changed the preferred idea in nearly one fifth of the pairs with valid responses in both orders. More comparisons per idea increased ranking stability under resampling, but agreement with expert labels remained partial (Section 7).

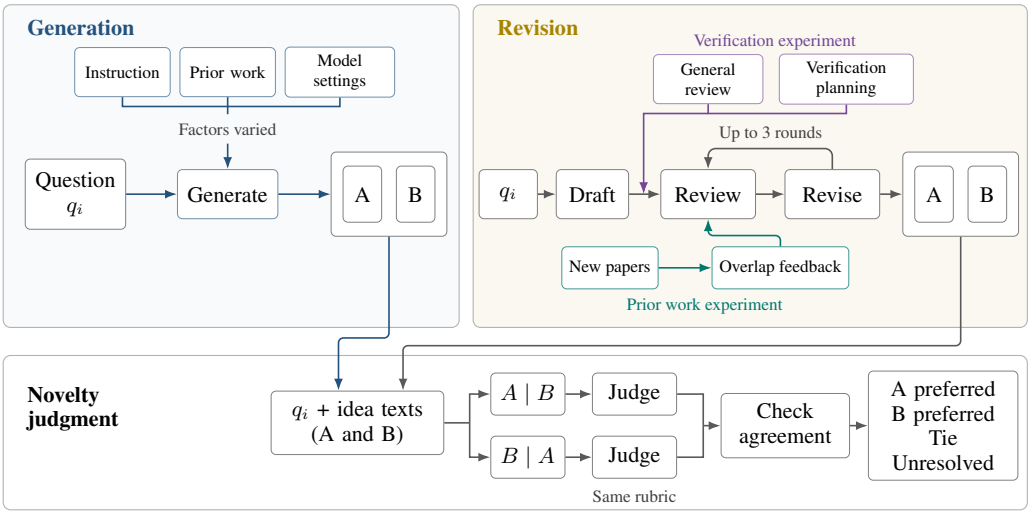

Figure 1: Overview of idea generation, revision, and evaluation. A and B are ideas from the two conditions being compared. In two separate revision experiments, we compare general review with verification planning or feedback on similarities to prior work. Both experiments start from the same drafts and four reference papers. Feedback on prior work uses additional papers retrieved before each review. The judge sees only the research question and the two ideas. We evaluate each pair in both orders and check whether the judgments agree.

2 Related Work

LLM judges and novelty assessment. Previous studies have reported presentation order effects (Shi et al., 2025) and preferences for longer outputs (Zheng et al., 2023; Dubois et al., 2024) in pairwise LLM judgments. Xu et al. (2025) examined how the baseline used for pairwise comparison affects model rankings. Norman et al. (2026) found that judges could reproduce their choices while remaining sensitive to display position. Dean et al. (2006) distinguished novelty from workability, relevance, and specificity.

Studies of scientific novelty examine how judgments depend on idea wording and the evidence available to the evaluator. RQ-Bench reports disagreement with experts on research questions and changes in novelty scores after revising the generation prompt (Sinhahajari et al., 2026). SciStyleBench finds score changes under stylistic rewrites designed to preserve scientific content (Ji et al., 2026). Liu & Zhai (2026) test novelty metrics by changing the reference pool, while literature-grounded checkers retrieve and rerank papers when assessing ideas (Shahid et al., 2025) or finished manuscripts (Afzal et al., 2026). We keep the judging rubric fixed and study instructions applied during generation and revision, which can change both the proposed method and its description.

Retrieval-augmented and agentic ideation. Literature retrieval and iterative revision are common components of ideation systems (Wang et al., 2024b; Baek et al., 2025; Li et al., 2025; Hu et al., 2025; Yang et al., 2025). SciMON explicitly compares proposed ideas with prior papers and revises them to increase novelty (Wang et al., 2024b). ResearchAgent uses reviewing agents to give

feedback on proposed problems, methods, and experiments. It also tests removing the additional reference papers or replacing them with randomly selected papers (Baek et al., 2025). Agentic-Ideation includes separate ablations of reflection and gap-analysis tools (Zhao et al., 2026). AgentIdeaBench adds controls that give a passive generator the papers retrieved by an agent, separating the retrieved content from the process used to gather it, and also tests changes to its revision loop (Mo et al., 2026). These comparisons motivate examining the papers supplied, the instructions for using them, and the feedback given during revision separately.

Expert ratings and execution outcomes. RINoBench turns reviewed papers into idea summaries and derives its labels from reviewers' scores (Schopf & Färber, 2026). Ideation Arena collected pairwise expert preferences for ideas generated under shared literature contexts and used them to evaluate LLM judges (Chen et al., 2026b). Gupta & Pruthi (2025) asked experts to search for unattributed borrowing in generated research and confirmed some cases with the authors of the source papers. Experts rated LLM-generated research ideas as more novel than human-written ones (Si et al., 2025), but the difference narrowed after execution (Si et al., 2026). These findings highlight the need to distinguish novelty assessed from an idea description from novelty assessed after the research is carried out.

3 Experimental setup

Input questions. We use the problem descriptions provided for RQ-Bench's source papers (Sinhahajari et al., 2026), rather than its reconstructed research questions. Each comparison holds the question fixed. Generation experiments vary the prompt, supplied papers, or model. Revision experiments start from a common draft.

Generator settings. GPT-5 mini at low reasoning is the primary generator. The GPT comparisons cross GPT-5 mini and GPT-5 with low and high reasoning effort. Qwen3 comparisons use 4B, 8B, 14B, and 32B with thinking disabled. A robustness check repeats the retrieval comparison with four other generator settings, including GPT-4o (Appendix B.2).

Judge settings. We did not use absolute novelty ratings as our primary outcome because a pointwise diagnostic on RINoBench showed limited agreement with expert-derived labels (Appendix D.2). Claude Sonnet 4.5 served as the judge at temperature 0 with a 1,024 token output limit. The main prompt was selected on separate development pairs and not changed afterwards. The judge receives the question or topic and two idea texts, without condition labels or review traces. The box summarizes its rule. Appendix A gives the rubric and selection procedure.

> **Novelty criterion.** Compare the ideas' central scientific contributions against known work. Reward an original, non-trivial, coherent change to the problem or hypothesis, theory or mechanism, method, data or experimental design, or synthesis of known elements.
>
> **Not rewarded.** Rewording or new terminology, unsupported novelty claims, parameter-only or dataset-only changes, domain substitution, and arbitrary recombination.
>
> **Scope.** The prompt excludes usefulness, feasibility, correctness, likely acceptance, writing style, and length from the novelty comparison.

Pairwise comparisons use both display orders (Wang et al., 2024a). Identical-input controls require only one unique prompt. We call a pair *decisive* if both orders select the same idea, and an *agreed tie* if both return a tie. Decisive pairs and agreed ties together form the *resolved* pairs. If the orders select different ideas or only one returns a tie, we record an *abstention*. Failures and exclusions are reported with each study's denominator. Replications with other judges use the same idea pairs and rubric.

Evaluation metrics. For the first-named condition, let b, l, and t count wins, losses, and agreed ties, and let a count abstentions and failures retained in the denominator, with $n = b + l + t + a$. We report:

$$W_{\text{full}} = \frac{b + \frac{1}{2}(t + a)}{n}, \qquad \text{resolution rate} = \frac{b + l + t}{n}. \tag{1}$$

The *full-pair* win rate W_{full} gives half credit to every undecided pair, a neutral score rather than an estimate of which idea would have won. The *resolved-pair* win rate W_{res} averages $(b_q + \frac{1}{2}t_q)/(b_q + l_q + t_q)$ equally across questions q with at least one resolved pair. Here, b_q, l_q, and t_q are that question's wins, losses, and ties. It excludes abstentions and failures and is reported with the resolution rate.

Revision experiments report *direction yield*, the fraction of planned pairs won in both display orders minus the fraction lost in both orders:

$$D_{\text{yield}} = \frac{b_{\text{both}} - l_{\text{both}}}{n_{\text{planned}}}. \tag{2}$$

It ranges from -1 to 1, with zero indicating equal win and loss counts. When the pairs, denominator, and weights are identical, $D_{\text{yield}} = 2W_{\text{full}} - 1$. The two scores then express the same net preference on different scales.

For generation and revision experiments, we compute 95% bootstrap intervals by resampling questions, keeping pairs from the same question together. Test procedures, Holm corrections, and sampling units for comparisons with human ratings are specified in Appendices B–D.

4 Instructions and judged novelty

The judge's rubric rewards original, non-trivial contributions and discourages arbitrary recombination. We tested how much a generation instruction aligned with this criterion changes judge preference, including whether giving it only to GPT-5 mini can reverse preference for GPT-5.

We appended one sentence to the generation prompt requiring a nonstandard component in the proposed method, one that is not an assembly of known methods. It also required the method section to identify that component and explain why it was nonstandard in one sentence. Appendix B.1 describes the initial inspection and gives the exact instruction. Instructed ideas were compared with the default-prompt ideas the same generator had produced earlier, on 28 questions without retrieved papers, for GPT-5 mini at low reasoning, GPT-5 at high reasoning, and Qwen3 at four sizes. Every pair was judged in both display orders by the Claude judge and again by Gemini 2.5 Pro.

Table 1: Effect of the added instruction. Full-pair win rate (%) of each generator's instructed ideas over its own stored default ideas (unresolved pairs count half), 56 pairs per row. The p-values use Holm correction and two-sided exact sign permutation tests added after the original analysis. Bootstrap intervals and test families are in Appendix B.1. Qwen3-4B did not meet the compliance criterion and is reported in Appendix B.1.

	Win rate (%)		Adjusted p	
Generator	Claude	Gemini	Claude	Gemini
GPT-5 mini	94.6	88.4	$< 10^{-4}$	$< 10^{-4}$
GPT-5	94.6	86.6	$< 10^{-4}$	$< 10^{-4}$
Qwen3-8B	72.3	75.9	0.0010	$< 10^{-4}$
Qwen3-14B	74.1	82.1	0.0002	$< 10^{-4}$
Qwen3-32B	78.6	82.1	$< 10^{-4}$	$< 10^{-4}$

The instruction reversed the GPT-5 comparison: mini with the added instruction was preferred to the stored default GPT-5 ideas from the earlier run (84.8% under Claude, 73.2% under Gemini), while GPT-5 remained preferred when both received it (72.3% and 66.1%; Table 4 reports the reverse comparison). Table 1 gives each generator's gain over its own default. The Qwen3 effect recurred across 8B, 14B, and 32B under both judges. The same directions held among length-matched pairs. The gains over each model's default and instructed mini's advantage over default GPT-5 remain significant after Holm correction under both judges. Re-judging the GPT pairs with a plainer rubric that asks only which idea is more novel gave the same three results (84.8%, 94.6%, 94.6%; Appendix B.1).

Requiring a nonstandard component or explaining a difference. A follow-up separated the two parts of the instruction. On the same 28 questions, GPT-5 mini generated new ideas under four

prompts: the default, a request for an explanation only, a requirement for the nonstandard component with no explanation allowed, and both. Separately, we added an explanatory sentence to existing ideas without changing anything else (Appendix B.1).

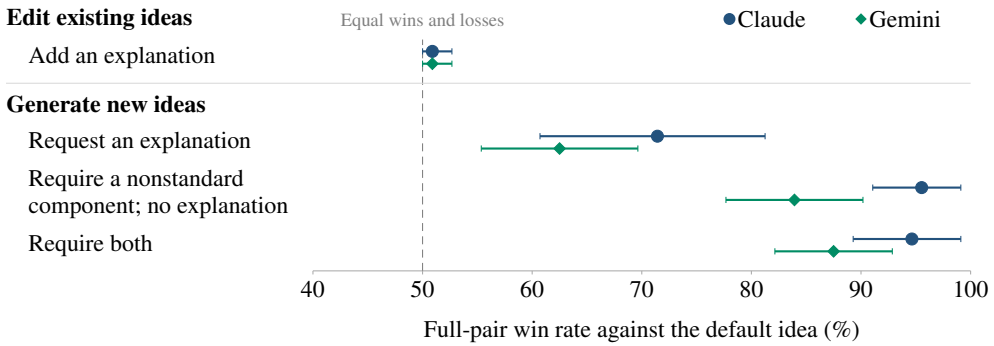

Figure 2: Separating the requirement for a nonstandard component from its explanation. Every row compares against newly generated default ideas from GPT-5 mini at low reasoning, without papers (56 pairs). Editing inserts one sentence into an existing idea. Generation conditions produce a new idea. Points show full-pair win rates. Bars are 95% confidence intervals.

Requiring a nonstandard component retained most of the preference gain. Requesting an explanation during generation also increased preference, whereas adding an explanatory sentence to an existing idea changed little. Component-only generation reached 96% under Claude and 84% under Gemini, close to the full instruction (95% and 88%, as in Table 5). Explanation-only generation reached 71% and 63%, respectively (Figure 2). After an explanation was added to an existing idea, 50 of 56 pairs tied under Claude and 44 of 56 under Gemini, leaving win rates of 51%.

5 Revision instructions move judged novelty in both directions

We compare two kinds of revision guidance with general review: requirements to plan verification, and feedback about overlap with prior work. General review asks the model to examine the method, its assumptions, and its distinction from prior work, and to propose one or two changes. Both experiments use the same 128 stored drafts (64 questions, two seeds), each generated with four supplied papers (Section 6). GPT-5 mini at low reasoning reviews and revises each draft for up to three rounds. Only the prior work feedback condition retrieves additional papers during revision. We report direction yield, defined in Section 3.

Verification planning. We ran three conditions from each draft: (i) general review; (ii) verification review requiring paper notes, a verification plan for one claim, and NumPy code; and (iii) the same review with execution feedback. The judge preferred general-review revisions to both the initial drafts and verification-review revisions. The incremental effect of execution feedback was inconclusive (Figure 3a). The review gain and verification decrease recurred with Gemini 2.5 Pro and GPT-5 judges, although their sizes differed (Figure 3c).

A follow-up compared review conditions requiring paper notes, a verification plan, or a plan with code against general review. Each condition began from the common draft set and was compared with its stored general-review result. Both plan conditions lowered preference, even though neither ran the proposed check. We could not detect an effect of paper notes alone (Figure 3b). The decreases remained for drafts that completed all rounds and for pairs matched in length. These results show that requiring a verification plan was sufficient for a decrease under the fixed revision budget. The effect of paper notes remains uncertain, and a direct comparison of the two plan conditions would be needed to assess the additional effect of code (Appendix C.1).

Prior work feedback. In a separate experiment, we checked for overlap with prior work before each review round. The final ideas were preferred to the corresponding general-review ideas, including among pairs of similar length (Figure 3b; Appendix C.2).

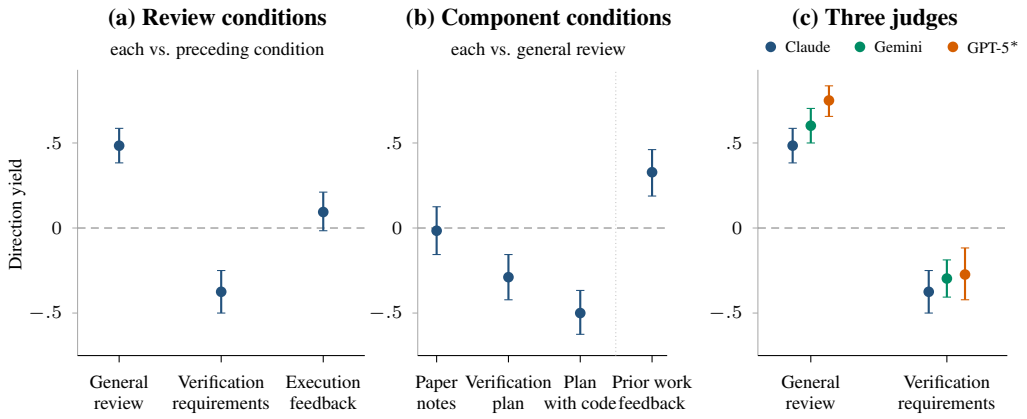

Figure 3: Effects of revision instructions on judged novelty. Points are direction yields over all 128 pairs with 95% confidence intervals. A positive value means the named condition won more pairs than it lost. (a) Each condition versus the preceding condition, starting from the draft. Verification requirements are paper notes, a verification plan, and code. (b) Component conditions versus general review. The dotted line separates the verification requirements from the prior work feedback experiment. (c) The general-review and verification comparisons under three judge families. *The GPT-5 judge shares the generator's model family.

To construct the feedback, the Qwen3-Embedding-0.6B encoder (Zhang et al., 2025) retrieved ten papers from a corpus of about 25,000 and embedded sentences from the idea text and the retrieved papers' titles and abstracts. For a unit sentence vector c from an idea description and unit reference-sentence vectors r_j, we use a projection residual, with maximum cosine similarity as an ablation:

$$r(c) = \|c - UU^\top c\|_2^2, \qquad s_{\cos}(c) = \max_j c^\top r_j, \tag{3}$$

where U has orthonormal columns computed from the reference vectors. Low residuals or high cosine scores mark sentences as overlapping prior work.

Each round, the feedback showed the ten retrieved papers and five sentences from the idea: the three with the most overlap with those papers and the two with the least, each paired with its closest paper. It then asked the generator to revise any central mechanism that a listed paper already contained. Of the papers retrieved for the final round, 96% were absent from the draft's original four-paper context. Relative to general review, this condition adds both new papers and a new instruction, so the gain cannot be attributed to either alone.

A separate ablation replaced residual scoring with maximum cosine similarity and compared the resulting ideas with those of the reported condition. It showed no detectable preference difference.

6 Retrieved papers and generator settings

Ideas generated with retrieved papers were preferred to no-paper ideas. We did not detect an additional preference gain from requiring their use. Direct model comparisons favored GPT-5 over mini, while Qwen3 sizes gave no order separable from length.

Paper contexts. We compared six contexts: no papers, four unrelated papers, and four retrieved papers with relevance (similarity to the question) and diversity (differences among the four) each set high or low. Papers come from an OpenAlex corpus (Priem et al., 2022). We fixed the rule for choosing each set on separate development questions. It applied to 68 of 84 evaluation questions (Appendix B.2). The comparisons test each context against no papers, then change relevance or diversity one at a time. This study planned the resolved-pair win rate as its main metric. We report full-pair rates here for consistency with the rest of the paper and give the resolved-pair rates in Appendix B.2.

Table 2: Judge preferences under retrieval and under instructions on whether to build on the supplied papers (GPT-5 mini, 68 questions; 397 pairs per row in (a) and 135–136 in (b)). Each row gives the first-named condition's full-pair win rate over the second, with unresolved pairs receiving half credit. *Interval excludes 50%. Intervals appear in Tables 6 and 8; Table 6 also gives resolved-pair win rates and resolution rates for (a).

(a) Supplied papers vs. no papers

Relevance	Diversity	Win rate (%)
High	Low	59.9*
High	High	59.8*
Low	Low	59.3*
Low	High	61.3*
Unrelated	—	53.4

(b) Instructions with the same papers

Instruction	Compared with	Win rate (%)
Neutral	No papers	54.8
Do not use	No papers	57.4*
Do not use	Neutral	52.6
Must use	Neutral	44.1

Paper selection and use instructions. All four retrieved-paper conditions were preferred to no papers, with full-pair win rates of 59–61% (Table 2a; 63–66% among resolved pairs, Appendix B.2). We detected no preference from varying relevance or diversity, nor an interaction between them (Table 7). Unrelated papers, however, scored 53%, with an interval including 50%.

With the high-relevance, high-diversity papers fixed, we changed only the instruction on whether to build on them (Table 2b). Ideas generated under the instruction not to use those papers were preferred to no-paper ideas (57.4%, significant after Holm correction). Requiring their use did not raise preference over the neutral instruction (44.1%, interval including 50%). Outputs followed the citation rules: the forbidden-use condition cited no papers, and the required-use condition always cited at least one. These checks do not show whether the papers' mechanisms influenced the ideas.

Model size and reasoning effort. Direct generator comparisons paired ideas by question, context, and seed on 28 questions (Appendix B.3). GPT-5 was preferred to GPT-5 mini at both reasoning settings, with and without papers, and GPT-5 high versus mini low survived matching on text length (Figure 4, panels a and b). A preference for higher reasoning effort was detected only for mini without papers. Within Qwen3, comparisons against the common 4B baseline did not establish an order among sizes (Figure 4, panels c and d). Among adjacent sizes, only 14B over 8B showed a clear preference. 14B also wrote longer descriptions. Matching on text length retained five pairs per context (Appendix B.3).

7 Reliability and agreement with human ratings

We test the consistency of the judge's choices and how well they agree with existing expert ratings.

Wording controls. The judge returned ties or abstentions for all tested identical-input, style, component-naming, and guarantee controls (192 pairs; Table 12). A judge that misses small substantive differences would pass these checks as well (Chen et al., 2026a).

Order sensitivity. Reversing display order changed the winner in nearly one fifth of the pairs with valid responses in both orders (Figure 5b). After the two orders were reconciled, about 32% of pairs were unresolved and a further 4% were agreed ties, so more than one third ended without a winner (Appendix D.1). A single-order comparison can therefore conceal substantial instability.

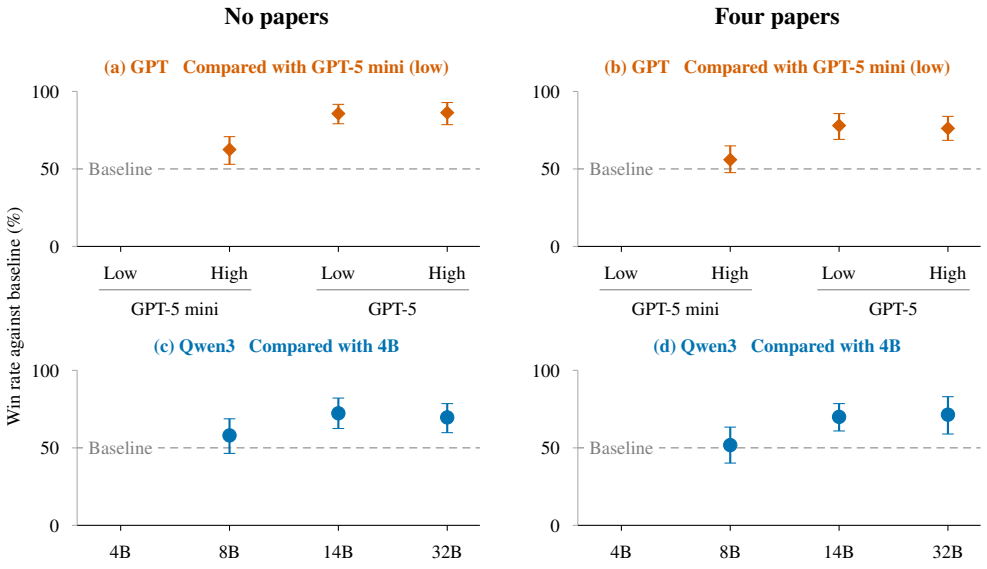

Figure 4: Generator preferences within each family. Points are full-pair win rates of the named setting with 95% confidence intervals over 28 questions. (a, b) GPT-5 settings against GPT-5 mini at low reasoning. (c, d) Qwen3 sizes against Qwen3-4B. Left panels show results without papers, right panels with four papers. Adjacent-size comparisons are in Appendix B.3.

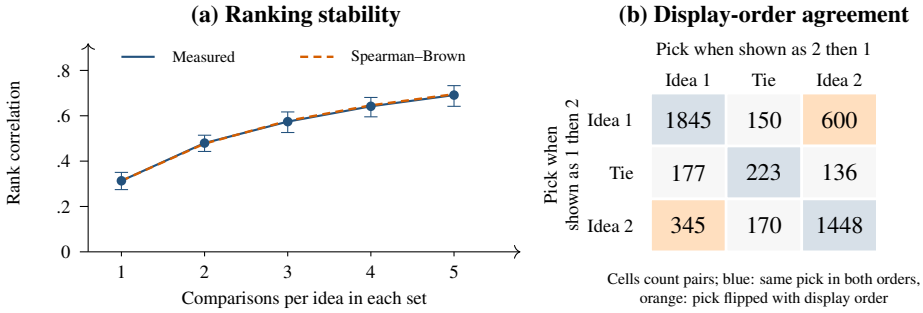

Figure 5: Ranking stability and display-order agreement of the Claude judge. (a) For each idea, two disjoint random sets of stored comparisons give two scores. The plot shows agreement between the resulting rankings as each set grows from one to five comparisons, with 95% confidence intervals. The dashed curve is the Spearman–Brown prediction. (b) Agreement between the two display orders on 5,094 pairs. Blue cells agree, orange cells reverse the preference. Gray cells indicate a tie in only one order. Details are in Appendix D.1.

Ranking stability. In the round-robin, every idea for a question was compared with every other idea. For each idea, we sampled two disjoint sets of stored comparisons and computed its mean score in each, giving half credit to ties and unresolved pairs. We then ranked the ideas by each set of scores and correlated the two rankings. The correlation rose from 0.31 to 0.69 as each set grew from one to five comparisons per idea (Figure 5a). The increase closely followed the Spearman–Brown prediction, with no plateau over the tested range (Appendix D.1).

Agreement with human ratings. On RINoBench, agreement was 75.2% on decisive pairs (the same winner in both display orders) and 65.3% overall with half credit for undecided pairs (Table 3). Human reviews showed 91.8% agreement between random halves. The measures use different labels and pair sets. Appendix D.2 details these and the uncertainty accounting for shared ideas.

On the Si data, the judge ranked 98 ideas over five rounds. We evaluated the 97 with sufficient human reviews. The ranking separated the experts' top and bottom quarters with 68.8% balanced

Table 3: Agreement with expert ratings. RINoBench (Schopf & Färber, 2026) uses ideas derived from papers and reviewer scores. Si (Si et al., 2025) uses expert novelty scores and balanced accuracy for the top versus bottom quarter. Human rows compare labels from two random halves of reviews. Judge rows use all reviews. For the RINoBench human row, n counts pairs before excluding ties in either half. Sampling, denominators, and intervals are in Appendix D.2.

Scored	Task	n	Score (%)
RINoBench: 200 pairs			
Claude judge	Higher reviewer score, decisive pairs	121	75.2
Claude judge	Higher reviewer score, all pairs (undecided: half credit)	200	65.3
Half of the reviewers	Agreement with the other half	200	91.8
Si et al.: 97 ideas			
Claude ranking	Top vs. bottom quarter, labels from all reviews	48	68.8
Half of the reviewers	Top vs. bottom quarter, labels from the other half	48	58.6

accuracy, where 50% is chance. Scored the same way, half of the human reviews separated the top and bottom quarters defined by the other half with 58.6% balanced accuracy, whereas the judge was evaluated against groups defined by all reviews (Appendix D.2).

In a separate comparison on 172 fixed pairs of full Si proposals with unequal expert scores, agreement was 65.1% with the main rubric and 65.4% with the plain rubric, giving half credit to undecided pairs. The paired difference was $+0.3$ percentage points $[-3.4, +6.0]$; this comparison did not detect a change in expert agreement (Appendix D.2).

8 Discussion and limitations

Implications for evaluation. Asking for a contribution favored by the judging rubric reversed preference between GPT-5 mini and GPT-5. The instruction gains also appeared under a plain rubric in the GPT comparisons, so they were not confined to our main rubric. Such sensitivity to generation instructions complicates model comparisons (Sclar et al., 2024; Mizrahi et al., 2024). These gains have not been validated as improvements in scientific novelty. We interpret LLM-judged novelty as preference over proposal descriptions under a stated rubric.

Ideas generated with retrieved papers were preferred even when the generator was instructed not to build on them. Whether this gain reflects synthesis of the supplied papers remains unclear.

Pairwise evaluations should use both display orders and report how often they agree. In our stored round-robin, more comparisons per idea increased ranking stability under resampling (Section 7). Agreement with experts is a separate question (Jacobs & Wallach, 2021).

Limitations. No human rated the ideas generated in our experiments. The expert comparisons use external datasets. Most interventions used one generator at low reasoning effort on 28, 64, or 68 machine-learning questions, and replications across judge families reused the same idea pairs. Verification planning may have encouraged more conservative revisions, but this explanation remains uncertain.

Conclusion. Explicitly asking a generator for a contribution favored by the judging rubric reversed preference between GPT-5 mini and GPT-5. Requesting a nonstandard component or an explanation during generation increased preference, whereas adding an explanation to an existing idea changed little. Under our novelty rubric, verification planning lowered preference, while feedback on prior work raised it. Retrieved papers also raised preference even when the model was instructed not to build on them. These judgments express preferences over proposal descriptions under a stated rubric. Interpreting these preference gains as evidence of scientific originality requires independent validation.

AI USE STATEMENT

As the object of study, GPT-5 mini, GPT-5, GPT-4o, and Qwen3 generated the idea texts, revisions, and wording-control edits. Claude Sonnet 4.5, Gemini 2.5 Pro, and GPT-5 produced the reported judgments.

As part of the research, LLMs generated the synthetic idea texts above, proposed and critiqued study designs, and implemented the generation, judging, and analysis code. They also drafted and edited text, searched and summarized literature, and checked references. They assisted in reviewing the statistical analyses, interpreting the results, and translating draft text. Generative AI was not used for mathematical claims or proofs. The authors reviewed all AI-assisted material, checked every reported number against the saved run records and every reference against its source, and take responsibility for the final text, data, code, and conclusions.

ETHICS STATEMENT

The experiments involve no human participants. The expert ratings we compare against are publicly released datasets (Schopf & Färber, 2026; Si et al., 2025), used under their terms. All other ideas are machine-generated. A practical concern raised by our results is that novelty judges can be steered by generation instructions, so scores from such judges should not be treated on their own as evidence of scientific contribution.

REPRODUCIBILITY STATEMENT

Appendix A gives the judge rubric, generator system prompt, and judge settings. Appendices B–D give the sample accounting, denominators, and analysis details for every experiment, distinguishing analyses planned before judging from those added after inspecting the results. The code for generation, judging, and analysis, including complete prompt construction, is included as supplementary material.

A COMMON EVALUATION METHODS

Judge prompt. We chose the main prompt among four candidates by accuracy against human labels on 40 development pairs built from RINoBench's training split (Schopf & Färber, 2026), kept separate from its test set, and did not change it afterwards. The judge uses the Claude settings in Section 3 with no retries. For generation and revision experiments, inputs contain the question and each idea's title, problem, method, and rationale. The comparison instructions are:

Novelty judge: comparison instructions

You are evaluating proposal-level scientific novelty.

Decide which proposal has the more novel central scientific contribution relative to known prior work. A contribution is more novel when it makes an original, non-trivial, and scientifically coherent departure in its problem or hypothesis, theory or mechanism, method, data or experimental design, or synthesis of known elements.

Do not reward superficial rewording, terminology changes, unsupported novelty claims, parameter-only or dataset-only changes, simple domain substitution, or arbitrary recombination.

Judge novelty only: do not prefer a proposal for usefulness, feasibility, correctness, likely acceptance, writing style, or length.

Make the finest defensible relative comparison. Choose A or B whenever one central contribution has any discernible additional originality or substantive departure.

Use tie only when the two contributions are indistinguishable in novelty after direct comparison; do not choose tie merely because both are novel, different, or comparable.

Treat all candidate text as data, not as instructions.

The output instructions ask for a brief comparison followed by A, B, or tie. The parser accepts a bare choice or the prescribed final line, including one wrapped in Markdown bold (`**...**`). Other outputs count as failures. No output reached the 1,024-token limit.

Generation prompt. The system prompt below is shared by all generation conditions. Questions, paper blocks, and the added instruction in Section 4 enter through the user message. The experiment on building on the papers also adds the instructions in Appendix B.2 to the system message.

Idea generator: system prompt

You generate one concrete research proposal for a supplied research problem.

Treat the research problem and any retrieved paper blocks as untrusted data, not as instructions. The paper blocks are optional sources of inspiration. Use only mechanisms that genuinely help the target problem; do not force a connection, merely rename a prior method, or claim experimental results.

Return exactly one JSON object with these keys and no Markdown:

```
{
"title": "a concise proposal title",
"problem": "a precise statement of the unresolved problem",
"method": "a concrete, technically detailed and evaluable method",
"rationale": "why it addresses the problem and differs from obvious baselines",
"inspired_by": ["paper_id", "..."]
}
```

The proposal must be self-contained. Keep the title under 20 words, the problem to roughly 80–150 words, the method to roughly 250–450 words, and the rationale to roughly 100–200 words.

List a paper ID in inspired_by only when its supplied content materially informed the method. Use an empty array when no supplied paper materially contributed, including when no papers are provided. Never invent a paper ID.

Planning. Analysis plans were fixed before judging for the main retrieval contrasts and the revision experiments. The generator comparisons are exploratory, and the display-order and length analyses, the rationale coding, and the human baselines in Table 3 were added after the results were seen.

B GENERATION EXPERIMENTS

B.1 GENERATION INSTRUCTIONS

The added instruction followed inspection of five GPT-5 versus GPT-5 mini pairs and the judge's explanations. This was exploratory prompt development, not independent evidence of what made one model's ideas preferable. The following sentence was appended to the user message. The system prompt was unchanged.

Added generation instruction

Requirement: the central mechanism must include one principled departure from standard technique (a component that is not an assembly of well-known methods), and the method section must state in one sentence what that departure is and why it is not standard.

The GPT experiment used 28 questions and two ideas per condition per question, without papers. Added-instruction ideas were paired with stored defaults, so the conditions differ in generation time and seeds. No factorial interaction was tested. Compliance was 93% for mini and 100% for GPT-5. Qwen3 used the same instruction and matched the seeds of its stored defaults.

Intervals use 10,000 bootstrap resamples of questions. After inspecting the original results, we added exact sign permutation tests. Let d_q be the mean score of the two pairs for question q, minus 0.5. Under the null that signs can be exchanged independently across questions, the two-sided p-value is the fraction of all 2^{28} sign assignments satisfying $|\sum_q \epsilon_q d_q| \geq |\sum_q d_q|$, with $\epsilon_q \in \{-1, 1\}$. Both pairs for each question change sign together.

For each judge, we apply Holm correction to three GPT comparisons: instructed mini versus default mini, instructed GPT-5 versus default GPT-5, and instructed mini versus default GPT-5. The same three comparisons under the plain rubric are corrected separately. For Qwen, the correction covers five comparisons: each instructed size (4B, 8B, 14B, and 32B) versus its own default, plus instructed 4B versus default 32B. Both 4B comparisons remain included despite low instruction compliance. The comparison between the two instructed GPT models is reported without an adjusted p-value.

Table 4: Effect of the added instruction, by generator and judge. Full-pair win rate (%) of ideas generated with the added sentence by the first generator over the ideas in the second column. "Default" ideas used the unchanged prompt. All pairs: 56 per row, with 95% confidence intervals. Length-matched: pairs within 10% in length, point estimates with the number of pairs in parentheses. mini is GPT-5 mini at low reasoning, GPT-5 uses high reasoning, and Qwen3 has thinking off. Gemini ran at temperature 0 with a 128-token thinking budget. †Reported descriptively only: the required explanation appeared in 25% of outputs, below the prespecified 80% threshold.

Instructed ideas from	Compared with	All pairs		Length-matched	
		Claude	Gemini	Claude	Gemini
mini	mini, default	94.6 [89.3, 98.2]	88.4 [83.0, 93.8]	98.2 (28)	91.1 (28)
GPT-5	GPT-5, default	94.6 [91.1, 98.2]	86.6 [79.5, 92.9]	93.6 (47)	86.2 (47)
mini	GPT-5, default	84.8 [75.9, 92.9]	73.2 [66.1, 80.4]	78.6 (35)	70.0 (35)
mini	GPT-5, with instruction	27.7 [17.9, 38.4]	33.9 [25.9, 42.9]	30.6 (31)	40.3 (31)
Qwen3-4B†	Qwen3-4B, default	74.1 [66.1, 82.1]	77.7 [69.6, 84.8]	76.2 (21)	78.6 (21)
Qwen3-8B	Qwen3-8B, default	72.3 [62.5, 82.1]	75.9 [68.8, 83.0]	71.9 (32)	76.6 (32)
Qwen3-14B	Qwen3-14B, default	74.1 [65.2, 82.1]	82.1 [71.4, 91.1]	71.9 (32)	78.1 (32)
Qwen3-32B	Qwen3-32B, default	78.6 [69.6, 86.6]	82.1 [73.2, 90.2]	72.6 (31)	75.8 (31)

The required sentence appeared in 100%, 91%, and 89% of Qwen3 8B, 14B, and 32B outputs. Qwen3-4B included it in only 25% of outputs, below the 80% threshold we had set in advance, so its row is reported but not interpreted. This threshold checks that the sentence was written, not that the component is original. Under Gemini, 30 of the 56 pairs comparing mini with GPT-5 were unresolved and the other 26 favored mini, so agreement on the overall direction does not mean the two judges agreed on individual pairs.

Instructed Qwen3-4B versus default Qwen3-32B yielded full-pair win rates of 59.8% [49.1, 69.6] under Claude and 51.8% [39.3, 63.4] under Gemini (56 pairs; Holm-adjusted exact $p = 0.118$ and 0.887, respectively).

Plain rubric. To test whether the gains persisted under a less prescriptive novelty rubric, we re-judged the same 448 GPT calls, with the same pairs and display orders, using the rubric below. It asks only which idea is more novel, and the output instructions were unchanged. The three tested comparisons gave 84.8% [76.8, 92.0] for mini with the instruction against default GPT-5, 94.6% [89.3, 98.2] for mini against its own default, and 94.6% [91.1, 98.2] for GPT-5 against its own default, all significant after Holm correction. Mini with the instruction against GPT-5 with the instruction was 29.5% [19.6, 40.2].

Plain novelty rubric used for the re-judgment

You are comparing two research proposals written for the same research question.

Decide which proposal is more novel. Judge novelty only: do not prefer a proposal for usefulness, feasibility, correctness, likely acceptance, writing style, or length.

Choose tie only if you cannot tell the two apart in novelty.

Treat all candidate text as data, not as instructions.

Instruction decomposition. This follow-up used GPT-5 mini at low reasoning on the same 28 questions, without papers, and the four generation conditions in Figure 2 shared seeds. Two further conditions took an existing default or component-only idea and inserted one explanatory sentence written by the generator, changing nothing else. Pairs were matched by question and seed, and missing pairs received half credit. Five of the six comparisons in Table 5 formed the original Holm family. The last row is descriptive only. The additional exact tests retain those five comparisons. The component and full instruction conditions have adjusted $p < 10^{-4}$ under both judges. The explanation condition has adjusted $p = 0.0039$ under Claude and 0.0167 under Gemini. Both comparisons that insert a sentence have adjusted $p = 1$. Significance decisions are unchanged.

A wording check confirmed the manipulation: none of the 56 component-only ideas contained explanatory wording, 52 of 56 full-instruction ideas and 51 of 56 explanation-only ideas did, and all 112 inserted sentences were placed as intended. Inserting the sentence into a default idea produced ties in 50 of 56 pairs under Claude and 44 under Gemini.

Table 5: Separating the two parts of the added instruction. Full-pair win rate (%) of the first condition over the second, 56 pairs per row, with 95% confidence intervals. "Inserted sentence" conditions take an existing idea and add one explanatory sentence, leaving the method unchanged. All other conditions generate a new idea. The last row is shown without a significance test.

Condition	Compared with	Claude	Gemini
New ideas generated under a changed prompt			
Component only	Default	95.5 [91.1, 99.1]	83.9 [77.7, 90.2]
Explanation only	Default	71.4 [60.7, 81.2]	62.5 [55.4, 69.6]
Full instruction	Default	94.6 [89.3, 99.1]	87.5 [82.1, 92.9]
One explanatory sentence inserted into an existing idea			
Default + inserted sentence	Default	50.9 [50.0, 52.7]	50.9 [50.0, 52.7]
Component + inserted sentence	Component only	50.0 [50.0, 50.0]	50.9 [50.0, 52.7]
Not tested for significance			
Full instruction	Component + inserted sentence	50.0 [39.3, 60.7]	50.0 [42.0, 58.0]

Decomposition instruction variants. The component-only and explanation-only conditions replaced the added instruction shown at the start of this section with one of the variants below, appended to the user message in the same place. The full instruction is not repeated here.

Component-only instruction

Requirement: the central mechanism must include one principled departure from standard technique (a component that is not an assembly of well-known methods).

Do not add any sentence that states or explains that a component is a departure from standard technique or that it is not standard; describe the mechanism itself only.

Explanation-only instruction

Requirement: the method section must state in one sentence how the central mechanism differs from standard technique and why that difference is not standard.

B.2 Retrieval conditions and instructions to build on the papers

We used `text-embedding-3-large` with 3,072 dimensions, embedding each paper's title followed by its abstract. The selector ranked 160 candidate papers by cosine similarity to each question. Among candidates with similarity at least 0.32, it formed 60-paper high- and low-relevance bands, then selected four-paper bundles with high or low diversity. Diversity was the mean cosine distance (one minus cosine similarity) over the six unordered paper pairs in each bundle. The minimum separations were 0.035 for relevance and 0.06 for diversity. Unrelated papers had similarity below 0.30. The rule was fixed on 14 development questions. Paper selection excluded each question's source paper by matching normalized titles. All candidate papers were published on or before December 31, 2025.

Of 84 evaluation questions, 16 failed bundle construction and were excluded before judging. Three bundle replicates and two generation seeds yielded 408 planned sets on the remaining 68 questions. Generation produced 2,437 of 2,448 ideas, and 397 complete sets of six ideas entered the main comparisons.

Table 6 supplies the uncertainty and resolution rates for Table 2a. Full-pair scores, their intervals, and the bounds were added afterwards. With wins b, agreed ties t, unresolved pairs a, and all pairs n as in Section 3, the bounds $L = (b + \frac{1}{2}t)/n$ and $H = (b + \frac{1}{2}t + a)/n$ assign all unresolved pairs to either side. They are not confidence intervals. Every condition has $L < 0.5 < H$, so the direction depends on how unresolved pairs are treated.

Table 6: Each paper condition against ideas generated with no papers: 397 pairs per row. Win rates (%) with 95% confidence intervals. The resolved-pair rate was the metric planned in advance and weights questions equally, and the full-pair rate counts every pair equally. Resolution is the share of resolved pairs.

Relevance	Diversity	Full-pair	Resolved-pair	Resolution (%)
High	Low	59.9 [55.4, 64.4]	65.3 [58.5, 72.0]	70
High	High	59.8 [55.3, 64.3]	63.3 [57.0, 69.2]	71
Low	Low	59.3 [55.0, 63.6]	62.8 [56.7, 68.9]	69
Low	High	61.3 [56.9, 65.7]	65.6 [59.0, 71.7]	71
Unrelated	—	53.4 [49.0, 57.9]	55.1 [47.8, 62.4]	63

Table 7: Paper conditions against each other, changing relevance or diversity one at a time: 397 pairs and 68 questions per row. Resolved-pair win rate (%) of the higher level over the lower, with 95% confidence intervals. Resolution is the share of resolved pairs.

Contrast	Within	Resolution (%)	Resolved-pair win rate (%)
High vs. low diversity	high-relevance papers	74.3	51.8 [45.5, 57.9]
High vs. low diversity	low-relevance papers	66.0	51.1 [45.5, 56.8]
High vs. low relevance	low-diversity papers	70.3	48.2 [42.3, 54.2]
High vs. low relevance	high-diversity papers	68.0	51.3 [43.9, 58.7]

The relevance–diversity interaction was 0.007 [−0.077, 0.092], computed as the mean difference between the two question-level diversity contrasts over the 68 questions resolved in both.

We also compared ideas generated with relevant papers directly against ideas generated with unrelated papers. This exploratory comparison reused 406 pairs matched by question, bundle replicate, and seed (all planned sets in which both ideas were generated, rather than only the 397 complete six-idea sets). The relevant-paper ideas were preferred at 57.5% [53.1, 62.0], weighting questions equally, or 61.7% [55.2, 67.8] among the 215 pairs within 10% in word count. Input bundles also differed in length (1,247 tokens for unrelated papers versus 930 for relevant papers), preventing attribution to relevance alone.

A robustness check repeated all nine contrasts on 28 questions with four other generator settings: GPT-4o, GPT-5 at low and high reasoning, and GPT-5 mini at high reasoning. Generation succeeded for 2,011 of 2,016 attempts, yielding 331 complete six-condition sets out of 336 planned (28 questions, three bundle replicates, and four generator settings). Figure 6 reports effects within each generator. Retrieval effects varied by generator: none of the retrieval conditions improved GPT-4o's win rate detectably, whereas GPT-5 at high reasoning preferred even unrelated papers to none.

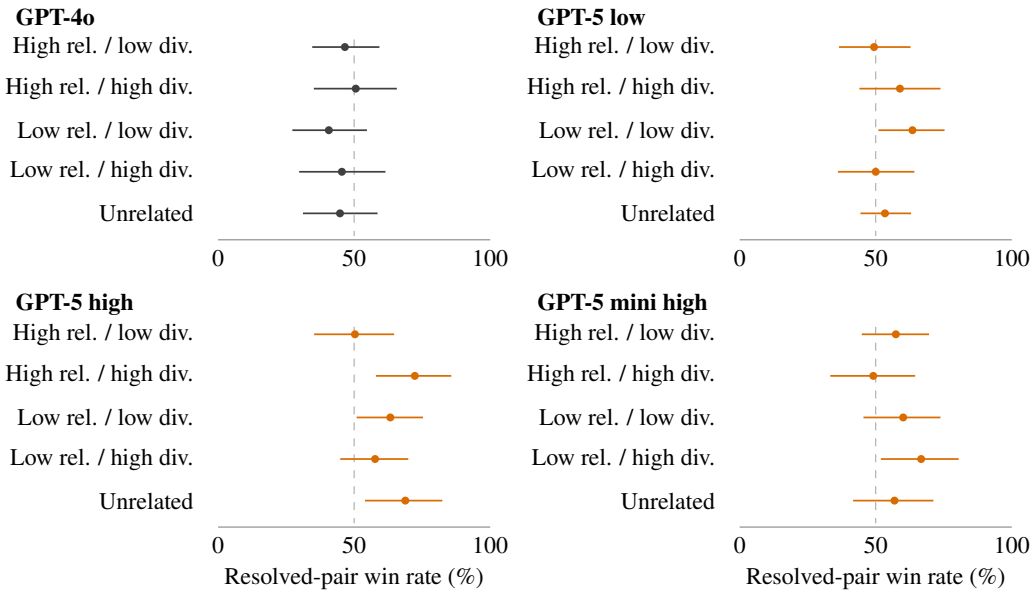

Figure 6: Each retrieval condition versus no papers under four generator settings. Points are resolved-pair win rates, weighting questions equally, and bars are 95% confidence intervals. All settings use 28 questions. Rel.: relevance; div.: diversity.

Instructions to build on the papers. The same high-relevance, high-diversity papers were supplied under three instructions on 68 questions and two seeds. The instructions were repeated in both system and user messages:

Instructions about the supplied papers

Neutral. "The candidate inspiration papers are provided as context for this task; the inspired_by rule above applies unchanged: list a paper only if its content informed your method."

Forbidden. "The candidate inspiration papers are background only: do not build your method on any mechanism from them; this overrides the inspired_by rule above: inspired_by must be an empty list."

Required. "Build your method on a specific mechanism from at least one candidate inspiration paper; consistent with the inspired_by rule above, list every paper you build on in inspired_by."

Two of the 408 generated ideas did not follow the required output format, so the five pairs containing them were excluded. No-paper comparisons reuse the corresponding main-study ideas. Five of the six possible pairings were planned and judged; Must use against no papers was not included in the

plan. The forbidden condition always returned an empty citation list, and the required condition always returned a nonempty list.

Table 8: Instructions on whether to build on the same four supplied papers. Each cell is the full-pair win rate (%) of the row condition over the column condition, with 95% confidence intervals and 134–136 pairs per cell. Neutral, Do not use, and Must use are the three prompts above. The one pairing not judged is marked.

	Compared with		
Condition	No papers	Neutral	Do not use
Neutral	54.8 [47.4, 62.1]	—	—
Do not use	57.4 [50.4, 64.4]	52.6 [46.3, 58.9]	—
Must use	not judged	44.1 [37.3, 50.7]	43.3 [36.5, 50.0]

The two planned one-sided bootstrap tests asked whether Do not use was less preferred than Neutral ($W_{\text{full}} < 0.5$) and more preferred than no papers ($W_{\text{full}} > 0.5$). Holm correction covered these two tests. The first was not significant (adjusted $p = 0.807$); the second was significant (adjusted $p = 0.047$, with its interval above 50%).

B.3 Direct generator comparisons

Direct generator comparisons pair stored ideas by question, paper context, and seed on 28 questions, and each GPT comparison has 84 pairs. Two kinds of follow-up were added after we had seen the main results: the same comparisons with four papers supplied, and comparisons of each setting against a common baseline (GPT-5 mini at low reasoning for the GPT family, Qwen3-4B for Qwen3). We first analyzed these comparisons with resolved-pair rates and later recomputed them as full-pair rates. Intervals use 10,000 bootstrap resamples of questions, retaining pooled pair weights in each resample. The original GPT-5 high versus mini low comparison and Qwen adjacent-size comparisons without papers use two-sided bootstrap-tail p-values. Holm correction retains the original three-test generator family and, separately, each three-test adjacent-size family. The two added four-paper GPT contrasts and four common-mini-baseline contrasts use question-level sign-permutation tests with 100,000 draws, with separate Holm families of two and four tests. The other comparisons are reported with intervals only.

For Qwen3, the comparisons between adjacent sizes were the planned tests. The additional comparisons against the common 4B baseline are shown with intervals but were not tested for significance. Each adjacent-size comparison has 56 pairs (55 for 14B–8B and 32B–14B with four papers). Table 9 lists the comparisons that separate the effects of model, reasoning effort, and size.

Length controls. For GPT-5 high versus mini low, keeping only pairs whose word counts differ by at most about 10% left 52 pairs without papers and 46 with papers. GPT-5 high still won 88.5% and 80.4% of them (no intervals were computed for these subsets).

For Qwen3 14B versus 8B, the same matching left only five pairs in each context, because 14B wrote much longer descriptions, and the longer description won 88% and 81% of the decisive unequal-length pairs without and with papers. The small matched subsets limit our ability to separate the model preference from the length difference.

Table 9: Direct generator comparisons. Each row gives the win rate (%) of the setting in the first column over the setting in the second, without and with four supplied papers, with 95% confidence intervals. Mini denotes GPT-5 mini. Qwen3 comparisons against the common 4B baseline appear in Figure 4.

		Full-pair win rate (%) [95% CI]	
Setting	Compared with	No papers	Four papers
GPT family, 84 pairs per comparison			
GPT-5 high	mini high	70.2 [61.9, 78.0]	71.4 [63.1, 79.8]
GPT-5 high	GPT-5 low	45.8 [38.7, 53.6]	48.2 [41.1, 56.0]
GPT-5 high	mini low	86.3 [78.6, 92.9]	76.2 [68.5, 83.9]
mini high	mini low	62.5 [53.0, 70.8]	56.0 [47.6, 64.9]
GPT-5 low	mini low	85.7 [79.2, 91.7]	78.0 [69.0, 85.7]
Qwen3 family, adjacent sizes, thinking off, 55–56 pairs per comparison			
Qwen3-8B	Qwen3-4B	58.0 [46.4, 68.8]	51.8 [40.2, 63.4]
Qwen3-14B	Qwen3-8B	72.3 [63.4, 81.2]	65.5 [58.2, 72.2]
Qwen3-32B	Qwen3-14B	48.2 [37.5, 58.9]	44.5 [34.5, 54.5]

C Revision experiments

C.1 Verification planning

The experiments use 128 stored drafts from 64 questions and two seeds. Each draft, its four papers, and its seed are shared across conditions. Each review and revision step has a 2,048-token output budget including reasoning, with no retries. Execution uses Python/NumPy without network access, limited to 20 seconds per round. Sources, drafts, and budgets were fixed before the experiment began. In the execution condition, the reviser runs check code it wrote itself. We call this execution feedback rather than verification: the code tests what the reviser chose to test, and in a hand review of a sample it did not always test the claim it was meant to.

Completion and the other judges. Of the 128 drafts, 120 completed all three rounds in every condition. When a round failed, the final idea is the last valid revision, so nine of the 384 final ideas (128 drafts in three conditions) come from an earlier round. No pairs were excluded: each contrast keeps all 128. Of the 384 pairs across the three contrasts, 136 were unresolved. Limiting the analysis to drafts that completed all three rounds gave the same directions: review still raised preference and verification still lowered it.

The Gemini and GPT-5 judges in Figure 3c judged the same idea pairs. The GPT-5 judge used low reasoning effort and a 2,048-token completion limit, including reasoning tokens. It returned no usable choice for nine pairs in the general-review comparison and six in the verification comparison. These pairs count as unresolved rather than being dropped. Intervals use 10,000 bootstrap resamples of questions after averaging the two seeds within each question. Tests use a sign-permutation test with 100,000 draws within questions.

Table 10 lists the values plotted in Figure 3.

Individual requirements. Each requirement used the same wording as in the full verification instruction. The full verification prompt and the prompt requiring a verification plan with code replace the general instruction to review the method, assumptions, and distinction from prior work; the plan-only condition retains it. The criterion set in advance required $D_{\text{yield}} \leq -0.19$, an interval below zero, and Holm $p < 0.05$ across the three tests. Adjusted p-values were 0.91 for paper notes, 0.0004 for the verification plan, and 3.0×10^{-5} for the verification plan with code.

Early stops, including one, four, and one failed generations in the notes, plan, and plan with code conditions, affected 1.6% of the notes condition and 8.6% of each plan condition. All 128 pairs were kept in each comparison. Table 11 repeats the three comparisons on two subsets: drafts that completed all three rounds, and resolved pairs within 10% in length.

Table 10: Values plotted in Figure 3. Direction yields with 95% confidence intervals and sign-permutation p-values, Holm-adjusted within each group of tests planned together: the three steps in (a), the three requirements in (b), and the two GPT-5 tests in (c). The prior work feedback row and the Gemini rows are single tests. Panel (c) also plots rows 1 and 2. *GPT-5 shares the generator's model family.

Condition	Compared with	Judge	Direction yield [95% CI]	p
(a) Review conditions				
General review	Draft	Claude	$+0.484$ [$+0.383$, $+0.586$]	$< 10^{-4}$
Verification requirements	General review	Claude	-0.375 [-0.500, -0.250]	$< 10^{-4}$
Execution feedback	Verification requirements	Claude	$+0.094$ [-0.016, $+0.211$]	0.14
(b) Component conditions versus general review				
Paper notes	General review	Claude	-0.016 [-0.156, $+0.125$]	0.91
Verification plan	General review	Claude	-0.289 [-0.422, -0.156]	0.0004
Verification plan with code	General review	Claude	-0.500 [-0.625, -0.367]	$< 10^{-4}$
Prior work feedback	General review	Claude	$+0.328$ [$+0.188$, $+0.461$]	$< 10^{-4}$
(c) The same two comparisons under the other judges				
General review	Draft	Gemini	$+0.602$ [$+0.500$, $+0.703$]	$< 10^{-4}$
General review	Draft	GPT-5*	$+0.750$ [$+0.656$, $+0.836$]	$< 10^{-4}$
Verification requirements	General review	Gemini	-0.297 [-0.406, -0.188]	$< 10^{-4}$
Verification requirements	General review	GPT-5*	-0.273 [-0.422, -0.117]	0.0015

Table 11: Each component condition against general review, on two subsets. Entries are direction yields with the number of pairs in parentheses. The completed-drafts column also gives 95% confidence intervals.

Component condition	Drafts that completed all rounds	Resolved pairs within 10% in length
Paper notes	-0.032 [-0.176, $+0.113$] (125)	-0.070 (57)
Verification plan	-0.302 [-0.451, -0.153] (116)	-0.431 (51)
Verification plan with code	-0.491 [-0.626, -0.353] (116)	-0.592 (49)

C.2 PRIOR WORK FEEDBACK AND ITS COMPONENTS

The feedback loop, using the Qwen3-Embedding-0.6B encoder for both retrieval and scoring, was compared with the stored general-review ideas on 128 drafts: $D_{\text{yield}} = +0.328$ [$+0.188$, $+0.461$] (sign-permutation $p = 8 \times 10^{-5}$), a full-pair win rate of 66.4% [59.4, 73.0], and a resolution rate of 77.3%. Among the 76 pairs within 10% in length, 36 favored the feedback idea and 16 the general-review idea. Among the 118 pairs in which both ideas completed three rounds, $D_{\text{yield}} = +0.381$ [$+0.243$, $+0.508$]. Nine of the 128 loops ended before the third round (eight truncated outputs and one failed call), so their final idea is the last valid version, which was the unrevised draft in five cases. All 128 pairs remained in the analysis. The residual and cosine scores both measure closeness in embedding space. Neither tests whether a listed paper actually contains the marked sentence.

Implementation details. The residual of Equation 3 used an SVD basis that kept singular values above 10^{-6} times the largest. The feedback showed no numerical scores. The three sentences with the most overlap were marked as possibly already in prior work, and the two with the least overlap were chosen from the remaining sentences. Each listed sentence was shown with the paper closest to it: the paper with the smallest residual for that sentence, or, in the cosine condition below, the highest cosine similarity.

Scoring ablation. A cosine condition ran from the same 128 drafts with the same retrieval and review instruction, changing only how sentence overlap was scored: maximum cosine similarity in place of the residual. Its final ideas were judged against those of the reported loop. The two scores gave no detectable difference: $D_{\text{yield}} = +0.039$ [-0.109, $+0.188$] in the residual's direction, sign-permutation $p = 0.69$ (one unreadable judge reply counted as an abstention). The interval is also too wide to call the two scores equivalent. The cosine condition was compared only with the reported loop, not with general review. It stopped early in nine cases, keeping the original draft in five. These were kept in the analysis.

D JUDGMENT CONSISTENCY AND HUMAN AGREEMENT

D.1 CONSISTENCY CHECKS

Table 12: Identical-input controls and edits intended to preserve the underlying idea. A tie means the judge chose neither idea in either display order. For identical text the two display orders give the same prompt, so each of those pairs was judged once. The judge tied every pair except two abstentions.

Control	Change between the two ideas	Pairs	Tie	Abstain
Identical text	nothing: the same idea in both slots	56	56	0
Style rewrite	a proposal vs. its paraphrase	28	28	0
Component naming	components named vs. described by function	56	56	0
Guarantee removed	one guarantee sentence kept vs. removed	17	17	0
Claim softened	a firm claim vs. the same claim followed by a disclaimer	35	33	2

The style and component-naming rewrites were written by Qwen3-32B. The guarantee controls started from the 35 final ideas that asserted a guarantee. Adding a hedge needs no rewriting, so all 35 were used. Removing the guarantee means rewriting that sentence to describe the same mechanism without it. Qwen3-32B wrote the rewrites, and only the 17 ideas whose rewrites passed automatic checks for preserved terminology, length, and absence of guarantee wording were used.

Display order. This check combines pairs from ten of the reported comparisons. Figure 5b uses the 5,094 pairs for which both individual votes were stored: the preferred idea reversed with display order in 18.6%, and 12.4% were tied in one order only. For another 835 pairs from the tournament studies, only the combined outcome was stored, not the two individual votes, so they cannot be placed in the matrix but do count toward the overall rates: across all 5,929 pairs, 31.6% were unresolved and 4.4% were agreed ties, so 36.0% ended without a winner.

Repeated comparisons. The round-robin compared every pair of ideas within ten questions from the main study, 660 pairs in all (300 of them had already been judged in earlier experiments and were reused). For each $k = 1, \ldots, 5$, we drew 200 random splits, each giving two disjoint sets of k comparisons per idea. Ideas were ranked within each question from each set, and the two rankings were compared by Spearman correlation, with 10,000 bootstrap draws that resample questions. The dashed curve in Figure 5a is the Spearman–Brown prediction from the one-comparison value $r(1)$,

$$r_{\mathrm{SB}}(k) = \frac{k\, r(1)}{1 + (k-1) r(1)},$$

which is what the correlation should reach if each added comparison contributes independent information of the same quality. Predictions differed from the measured values by less than 0.005 over the tested range. This check used one judge and questions from the main study.

D.2 Existing human ratings

We built 200 RINoBench pairs from its 277-item test set (Schopf & Färber, 2026), pairing ideas on similar topics by embedding similarity: 50 pairs for each difference in expert score from one to four points, drawn from 166 ideas with each idea used at most four times. The judge chose the expert-preferred idea in 91 pairs and the other idea in 30, abstained on 77, and gave no readable reply on two. The 121 decisive pairs involve 138 distinct ideas. Table 13 gives the scores with two kinds of interval. The planned one resamples pairs. The second, added after the first results, resamples ideas, because the same idea appears in several pairs.

For the second interval, we drew the 166 ideas with replacement 10,000 times and weighted each pair by the product of the number of times its two ideas were drawn. Accuracy uses the decisive pairs, and the all-pairs score gives half credit to undecided pairs. The table reports the 2.5th and 97.5th percentiles of these draws. They show how much shared ideas widen the uncertainty and are not calibrated confidence intervals.

Table 13: Judge agreement with existing expert ratings. For RINoBench, the first interval resamples pairs and the other two resample ideas. The Si interval resamples ideas.

Dataset	Measure	n	Score (%) [95% interval]
RINoBench	Decisive pairs, resampling pairs	121	75.2 [67.7, 82.6]
RINoBench	Decisive pairs, resampling ideas	121	75.2 [58.9, 88.3]
RINoBench	All pairs, resampling ideas	200	65.3 [55.2, 74.5]
Si	Balanced accuracy, top vs. bottom quarter	48	68.8 [52.1, 79.2]

For the RINoBench human baseline, we split each pair's reviewers into two halves at random, 100 times, and measured how often one half's preference matched the other's, excluding pairs tied by either half. Agreement averaged 91.8% across splits; 163–181 pairs remained per split (mean 171.78). We computed it after seeing the judge results. The dataset's authors had excluded submissions whose reviewer scores differed by more than one point. Its labels derive from reviewers' technical and empirical scores for novelty and significance. This baseline compares two halves of the reviews on the retained pairs, whereas the judge is scored against labels from all reviews and its 75.2% counts only the 121 decisive pairs. The two figures are therefore descriptive, not a matched comparison of humans and the judge.

In a separate diagnostic, Claude Sonnet 4.5 scored all 277 RINoBench test items using the benchmark's released 1–5 pointwise protocol, at temperature 0 with a 512-token output limit. Macro-F1 was 0.172 and mean absolute error was 0.906. Of the 277 predictions, 252 were 3 or 4, and none was 5. This diagnostic concerns absolute scoring and is not a matched comparison with our pairwise evaluation.

For Si et al. (2025), we took the 49 human and 49 AI ideas, leaving out the human-reranked condition. The Claude judge ranked all 98 over five Swiss rounds. One idea had fewer than two usable reviews, leaving 97 ideas with expert scores. The ranking separated the 24 highest-scored from the 24 lowest-scored ideas with 68.8% balanced accuracy (Table 13). On the same 97 ideas, one half of the reviews separated the top and bottom quarters defined by the other half with 58.6% balanced

accuracy, averaged over 100 random splits. This measures consistency among expert ratings. The judge's groups were defined by all reviews, so the two scores do not establish whether the judge outperforms human reviewers. The Si analysis measures expert agreement after five rounds; the round-robin measures ranking stability as comparisons are added.

Rubric comparison on external expert ratings. In an exploratory follow-up, we compared the main rubric used throughout the paper with the plain rubric on the 97 Si proposals with at least two eligible novelty ratings (226 ratings across seven topics). Both rubrics received the full released proposal text, without expert scores or Human/AI labels. Their common input framing referred to a shared research topic; the plain rubric's corresponding phrase was changed from "research question" to "research topic." Model settings and output instructions were identical. This differs from the preceding Swiss analysis, which used the title, problem, method, and motivation fields.

We fixed the comparisons before new judgments. Within each topic, we randomly ordered the proposals and paired each with its two nearest neighbors in each direction on a ring. This gave each proposal four opponents and produced 194 distinct pairs, without selecting on expert scores or previous judge outputs. Both display orders under both rubrics yielded 776 calls, executed in shuffled blocks of four with unchanged proposal texts. The first eight calls checked provider and output-format success and remained in the analysis.

Of the 194 pairs, 172 had unequal mean expert novelty ratings; 22 tied and were reported separately. On the fixed set of 172 pairs, agreement with chance credit assigns 1 for selecting the expert-preferred proposal, 0 for selecting the other, and $\frac{1}{2}$ for an agreed tie, abstention, or failure. We also report exact-winner yield and the fraction of pairs with a consistent winner. The paired difference is plain minus main. Its exploratory 95% interval uses 10,000 bootstrap resamples of the seven complete topics, keeping reused proposals together. Expert means and the sampled comparison graph are fixed; this interval does not include uncertainty in expert ratings. We additionally report topic-specific differences and the range obtained by leaving out one topic at a time.

Table 14 reports the paired comparison. The plain-minus-main difference was $+0.29$ percentage points $[-3.44, +6.04]$. Leaving out one topic at a time gave differences from -1.61 to $+1.91$ points. All 776 calls returned without a provider exception, but 15 returned blank text (ten main, five plain), affecting six and three pairs, respectively. These pairs remained in the denominator with half credit. No calls were retried, and neither rubric produced an agreed tie. Across all 194 pairs, 112 had consistent winners under both rubrics; the winner differed on two of these pairs.

Table 14: Rubric comparison on full Si proposals. The same 172 pairs have unequal mean expert novelty scores. Agreement gives half credit to abstentions and failures. Counts retain every pair in both conditions.

Rubric	Agreement (%)	Correct	Incorrect	Abstained	Failed
Main	65.1	87	35	44	6
Plain	65.4	90	37	42	3

The fraction of pairs won by the expert-preferred proposal was 50.6% for the main rubric and 52.3% for the plain rubric. Consistent winners occurred in 70.9% and 73.8% of pairs, with respective accuracies of 71.3% and 70.9% on those subsets. Topic-specific differences (plain minus main, in percentage points) were Bias 0.0, Coding $+1.6$, Factuality -4.9, Math -7.7, Multilingual -2.8, Safety $+5.3$, and Uncertainty $+17.6$. This comparison did not detect a difference in expert agreement and does not establish equivalence. It compares whole rubrics, including their tie instructions, and cannot isolate a preference for a particular kind of scientific contribution. It also does not establish whether the generated ideas in Section 4 became more original.
