CoCoUN: Full-Trace Concept Unlearning in Multimodal Reasoning Models

Anonymous authors
Paper under double-blind review

Abstract

Machine unlearning in multimodal reasoning models aims to remove specific concepts while preserving general reasoning ability. However, existing methods focus primarily on final answers, overlooking target concepts disclosed in the preceding chain of thought. We reveal that this answer-centric paradigm leaves a systematic leakage path: once a target is generated as a discrete reasoning token, it becomes both visible output and autoregressive context for subsequent generation. Based on this insight, we propose CoCoUN, a novel full-trace concept-unlearning framework that removes a target before its discrete realization. CoCoUN replaces the target span with an adaptive continuous trajectory before its first token is emitted. Its joint objective learns the discrete-to-continuous transition, unlearns the target throughout the trajectory, and preserves subsequent reasoning through latent-exit continuation learning. Extensive experiments across multimodal reasoning backbones and diverse visual concepts demonstrate that CoCoUN substantially outperforms existing methods in full-trace unlearning while maintaining strong performance on unrelated tasks.

1 Introduction

Multimodal large reasoning models (MLRMs) (Team, 2025; Yao et al., 2025) have achieved strong performance on tasks that require joint visual understanding and multi-step reasoning. Powered by large-scale multimodal pretraining, these models can also memorize and reproduce sensitive, copyrighted, or harmful information. To mitigate these risks, machine unlearning (Cao & Yang, 2015; Bourtoule et al., 2021) aims to remove specified information from a trained model while preserving its general capabilities. Existing studies adapt unlearning to multimodal models through optimization, parameter editing, or activation steering (Huo et al., 2025; Liu et al., 2025b; Li et al., 2025), and evaluate whether the target remains recoverable primarily from the final answer.

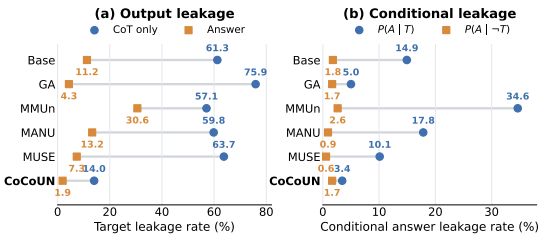

Figure 1: **Reasoning leakage across unlearning methods.** T and A denote target hits in the reasoning trace and answer, respectively.

The evaluation of current unlearning methods centers on whether the target is absent from the final answer. However, this criterion overlooks the explicit reasoning trace generated before an MLRM reaches its conclusion (Kakkar et al., 2026; Wei et al., 2022). As shown in Figure 1(a), the target frequently appears only in the trace across the base model and existing methods, allowing a model to pass answer-level evaluation while directly disclosing the forgotten concept. We therefore formulate *full-trace concept unlearning*, which requires removing the target from both the reasoning trace and final answer while retaining performance on unrelated tasks.

Full-trace unlearning is further complicated by the autoregressive nature of reasoning generation. Once a target token is sampled, it becomes part of the context used to generate subsequent tokens (Lanham et al., 2023; Turpin et al., 2023). As shown in Figure 1(b), answer leakage becomes substantially higher when the target has already appeared in the reasoning trace. This indicates that

Reviewers: please read the Reviewer Guidelines (iclr.cc/Conferences/2027/ReviewerGuidelines) and the AI Policy for Reviewers (iclr.cc/Conferences/2027/AIPolicyForReviewers). If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.

suppressing the target after its discrete generation cannot prevent its influence on the rest of the reasoning process. To address this problem, we introduce *CoCoUN*, a full-trace concept-unlearning framework that intervenes immediately before the target's first discrete realization. CoCoUN replaces the target span with an adaptive continuous trajectory and learns a latent transition that moves from ordinary discrete decoding into this trajectory. The causal decoder then recurrently updates the latent states while a trajectory-level objective suppresses target recoverability at every step. A latent-exit continuation objective distills the non-target next-token distribution, allowing ordinary discrete decoding to resume after the intervention. By preventing the target from becoming either visible output or autoregressive context, CoCoUN removes the source of trace leakage while preserving the subsequent reasoning process.

In summary, our contributions are threefold. **(i)** We identify the gap between answer-level and full-trace unlearning in MLRMs and formulate an evaluation protocol that measures target recovery from the complete reasoning output. **(ii)** We propose CoCoUN, which performs concept unlearning through a learned latent transition, an adaptive continuous trajectory, and latent-exit continuation. **(iii)** We demonstrate effective full-trace unlearning with retained multimodal reasoning across two backbones, named and safety concepts, and diverse recovery attacks.

2 Related Work

Machine unlearning for multimodal generative models. Machine unlearning removes selected data or concepts without full retraining, covering exact deletion, approximate deletion, and statistical indistinguishability (Cao & Yang, 2015; Ginart et al., 2019; Guo et al., 2020; Bourtoule et al., 2021; Neel et al., 2021). Recent work emphasizes scalable post-hoc updates and verification (Sekhari et al., 2021; Blanco-Justicia et al., 2025; Wang et al., 2024; Xu, 2024). Practical methods for generative models include gradient ascent, generic relabeling, preference-style updates, and localized parameter editing (Eldan & Russinovich, 2023; Yao et al., 2024; Maini et al., 2024; Huang et al., 2025; Wang et al., 2025; Cha et al., 2025; Tian et al., 2024). MMUnlearner and modality-aware neuron pruning extend these ideas to vision-language models, while R-MUSE targets reasoning preservation in MLLMs (Huo et al., 2025; Liu et al., 2025b; Li et al., 2025). However, lexical suppression remains vulnerable to prompt transformations and recovery attacks (Jang et al., 2025; Zou et al., 2023; Chao et al., 2025). Existing evaluation mainly checks final-answer availability and retained utility, while reasoning models expose an additional channel through which intermediate tokens can recover the target. We therefore extend unlearning from the answer distribution to the full autoregressive trace and locate the update at the target's first realization.

Chain-of-thought and latent reasoning. Chain-of-thought prompting externalizes intermediate language and improves reasoning performance (Wei et al., 2022; Kojima et al., 2022; Wang et al., 2023). Search-based methods further expand the trace through tree- or graph-structured thoughts (Yao et al., 2023; Besta et al., 2024), while recent work shows that useful reasoning need not be fully verbalized (Zelikman et al., 2024; Wang, 2026). Latent reasoning instead uses recurrent hidden states, looped latent thoughts, compressed rationale states, or predicted latent variables (Hao et al., 2024; Saunshi et al., 2025; Tan et al., 2025; Chen et al., 2026); soft prompts and intermediate representations likewise serve as computational interfaces (Li & Liang, 2021; Lester et al., 2021). Recent multimodal studies examine the transition from discrete tokens to continuous states and highlight latent bypass, weak downstream use, and representation collapse as key failure modes (Viveiros et al., 2026; Wang, 2026). Our setting differs in both objective and locality: continuous computation is inserted only at the target-bearing interval and optimized for unlearning, while the surrounding CoT remains ordinary text. This design makes the trajectory trainable from forget spans and testable through target recoverability, retention, and causal use by subsequent tokens.

3 Task Definition

An MLRM f_θ receives visual input v and query q, then generates a reasoning trace r followed by an answer a,

$$f_\theta(v, q) = y = (\texttt{<think>}, r_1, \ldots, r_m, \texttt{</think>}, a_1, \ldots, a_n). \tag{1}$$

Under the interface in Equation (1), let $\mathcal{D}_f^c$ contain target-bearing examples for concept c and $\mathcal{D}_r$ contain retained examples. Unlearning adapts f_θ to f_{θ_c} so that c is absent from the complete gener-

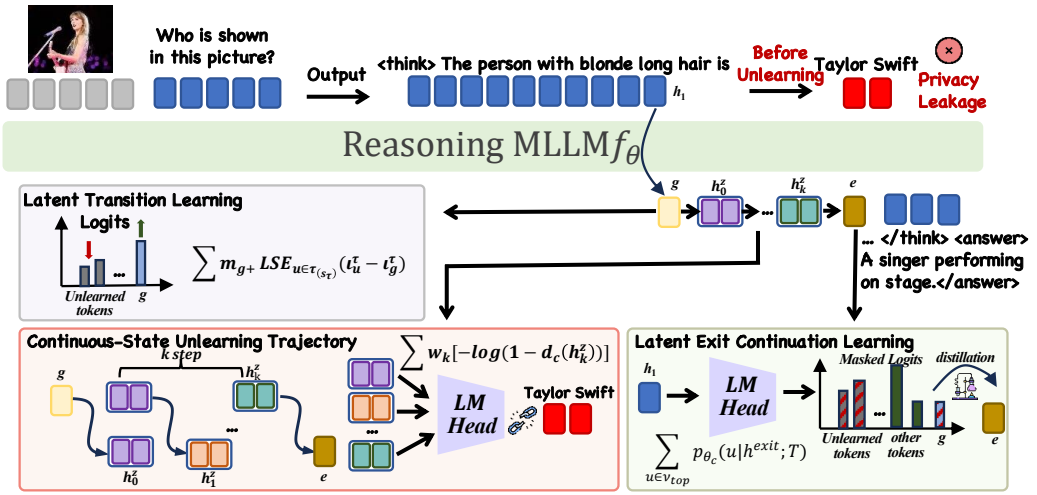

Figure 2: **Overview of CoCoUN.** Top: ordinary autoregressive reasoning emits the target concept as visible text and reuses it as context for subsequent generation, leading to trace and privacy leakage. CoCoUN instead intervenes immediately before the target's first discrete realization, replacing the target span with an adaptive continuous trajectory and resuming discrete decoding from its latent exit. Bottom: the three coupled objectives learn the discrete-to-continuous transition, suppress target recoverability throughout the recurrent trajectory, and distill the masked non-target distribution for latent-exit continuation.

ation on $\mathcal{D}_f^c$ while behavior on $\mathcal{D}_r$ is preserved. With $H_c(y) \in \{0, 1\}$ denoting target recovery from y and $D(\cdot\|\cdot)$ denoting behavioral deviation, we write

$$\min_{\theta_c} \mathbb{E}_{(v,q)\sim\mathcal{D}_f^c} H_c(f_{\theta_c}(v, q)) \quad \text{s.t.} \quad \mathbb{E}_{(v,q)\sim\mathcal{D}_r} D(f_{\theta_c}(v, q)\|f_\theta(v, q)) \le \epsilon. \tag{2}$$

Unlike answer-only unlearning, H_c in Equation (2) covers both r and a.

4 Method

4.1 CoCoUN Overview

Figure 2 summarizes CoCoUN. Let τ denote the first position at which concept c would be verbalized, and let $\mathcal{T}_c$ be the set of vocabulary ids expressing the target. Before τ, the target is represented only in the multimodal hidden state; once y_τ is sampled, it becomes visible and conditions all subsequent tokens. CoCoUN therefore intervenes before this first discrete realization: it enters a continuous trajectory at the target-bearing state, recurrently transforms the resulting latent states, and resumes text generation from the latent exit.

Autoregressive generation factorizes as

$$p_\theta(y \mid v, q) = \prod_t p_\theta(y_t \mid v, q, y_{<t}). \tag{3}$$

Specifically, let h_τ^- denote the final hidden state under the multimodal prefix $x_{<\tau} = (v, q, y_{<\tau})$. With $\mathcal{V}$ denoting the tokenizer vocabulary and $W_{\text{LM}} \in \mathbb{R}^{|\mathcal{V}|\times d}$ the language model head, we write

$$\ell_u(h) = (W_{\text{LM}}h)_u, \qquad p_\theta(u \mid h) = \frac{\exp\big(\ell_u(h)\big)}{\sum_{w\in\mathcal{V}} \exp\big(\ell_w(h)\big)}. \tag{4}$$

CoCoUN jointly learns to enter the latent trajectory, suppress target recoverability along its states, and restore a natural non-target continuation after the latent exit.

4.2 FORGET-AWARE TRAJECTORY CONSTRUCTION

We first turn naturally occurring concept mentions into supervised unlearning trajectories. For an assistant reasoning trace $r = (r_{<\tau}, s, r_{>\tau+|s|})$, where span s realizes the target, we replace the target span with a latent interval:

$$\begin{aligned} \Phi_c(r) &= \big(r_{<\tau}, g, z_1, \ldots, z_K, e, r_{>\tau+|s|}\big), \\ g &= \texttt{<|latent_start|>}, \qquad e = \texttt{<|latent_end|>}. \end{aligned} \tag{5}$$

The positions $z_{1:K}$ receive recurrent hidden states as input instead of word embeddings. Their labels, as well as the label of e, are masked; g serves as the discrete transition target, while unaffected assistant tokens retain weak language-model supervision. The removed token ids $\mathcal{T}(s)$ define the target set used for trajectory-level forgetting.

Under the prefix that originally predicted the first token of s, the transformed trace predicts g rather than a target token. Each target occurrence therefore provides direct supervision for the location at which continuous unlearning begins.

4.3 LEARNING THE LATENT TRANSITION

We train CoCoUN to emit g at the position where the target span would otherwise begin:

$$\mathcal{L}_{\text{start}} = -\frac{1}{|\mathcal{B}_c|} \sum_{(x,\tau)\in\mathcal{B}_c} \log p_{\theta_c}(g \mid x_{<\tau}), \tag{6}$$

where $\mathcal{B}_c$ contains transformed training sequences and the start position τ of each replaced target span. Cross-entropy alone can increase the probability of g without making it more likely than the target tokens it replaces. We therefore enforce a margin between the transition logit and the aggregate target-token score. Let ℓ_u^τ denote the logit of token u at position τ. For margin $m_g > 0$, we optimize

$$\mathcal{L}_{\text{margin}} = \frac{1}{|\mathcal{B}_c|} \sum_{(x,\tau)\in\mathcal{B}_c} \big[m_g + \text{LSE}_{u\in\mathcal{T}(s_\tau)}\, \ell_u^\tau - \ell_g^\tau\big]_+ . \tag{7}$$

This loss vanishes once the transition logit exceeds the aggregate score of the removed target tokens by m_g. Together, Equations (6) and (7) learn to enter the continuous trajectory before target lexicalization.

4.4 CONTINUOUS-STATE UNLEARNING TRAJECTORY

Emitting g initiates a continuous unlearning trajectory computed by the same causal decoder. Let h_0^z denote the hidden state produced after consuming the transition symbol g. At latent step k, the preceding hidden state is fed back as the next input embedding:

$$e_k^z = h_{k-1}^z, \qquad h_k^z = F_{\theta_c}(e_k^z; \text{KV}_{<\tau+k}), \qquad k = 1, \ldots, K. \tag{8}$$

The cache $\text{KV}_{<\tau+k}$ contains the visual input, query, preceding CoT, transition symbol, and previously generated latent states. This recurrent construction adapts the trajectory to each example while preserving causal access to the original prefix.

At every latent state, we measure target recoverability through the language model head:

$$d_c(h_k^z) = p_\theta(\mathcal{T}_c \mid h_k^z) = \sum_{u\in\mathcal{T}_c} p_\theta(u \mid h_k^z). \tag{9}$$

We then minimize the target mass along the entire trajectory:

$$\mathcal{L}_{\text{forget}} = \frac{1}{\sum_{k=1}^K w_k} \sum_{k=1}^K w_k \big[-\log(1 - d_c(h_k^z))\big]. \tag{10}$$

The nondecreasing weights $w_1 \le \cdots \le w_K$ apply stronger forgetting pressure toward the latent exit while supervising every recurrent state. Thus, unlearning is performed as a trajectory-level transformation rather than as a single-step suppression at the target position.

4.5 LATENT-EXIT CONTINUATION LEARNING

The latent exit should preserve the non-target continuation available immediately before the target span. Let h_τ^- denote the hidden state at that position. We first define the model's pre-target distribution and the set of target and latent symbols to be removed:

$$p_\tau^-(u) = p_{\theta_c}(u \mid h_\tau^-), \qquad \mathcal{S}_c = \mathcal{T}_c \cup \{g, z, e\}. \tag{11}$$

We retain the high-probability non-target alternatives by restricting the support to $\mathcal{V}_{\text{top}} \setminus \mathcal{S}_c$ and renormalizing the corresponding logits:

$$q_c(u) = \text{sg}\left[\frac{\exp(\ell_u(h_\tau^-)/T)}{\sum_{j \in \mathcal{V}_{\text{top}} \setminus \mathcal{S}_c} \exp(\ell_j(h_\tau^-)/T)}\right], \quad u \in \mathcal{V}_{\text{top}} \setminus \mathcal{S}_c. \tag{12}$$

Here, h^{exit} is the final state of the transformed trajectory. The latent-exit continuation objective distills this masked distribution:

$$\mathcal{L}_{\text{exit}} = -T^2 \sum_{u \in \mathcal{V}_{\text{top}} \setminus \mathcal{S}_c} q_c(u) \log p_{\theta_c}(u \mid h^{\text{exit}}; T). \tag{13}$$

Here, $T > 0$ is the distillation temperature, and sg denotes stop-gradient, preventing gradients from flowing through the same-model reference distribution. A weak continuation cross-entropy term initializes grammatical re-entry, while Equation (13) preserves multiple non-target next-token alternatives at the latent exit.

The three mechanism losses are combined with language-preservation and auxiliary regularization terms into the complete training objective:

$$\begin{aligned}\mathcal{L}_{\text{CoCoUN}} = \lambda_{\text{ce}}\mathcal{L}_{\text{CE}} + \lambda_{\text{start}}\mathcal{L}_{\text{start}} + \lambda_{\text{margin}}\mathcal{L}_{\text{margin}} \\ + \lambda_{\text{forget}}\mathcal{L}_{\text{forget}} + \lambda_{\text{exit}}\mathcal{L}_{\text{exit}},\end{aligned} \tag{14}$$

where $\mathcal{L}_{\text{CE}}$ preserves unaffected assistant tokens.

4.6 AUTOREGRESSIVE UNLEARNING INFERENCE

During inference, CoCoUN follows the decoding strategy used by the underlying model until it emits the transition symbol g. For greedy decoding, the next token is selected as

$$\hat{y}_t = \arg\max_{u \in \mathcal{V}} p_{\theta_c}(u \mid v, q, r_{<t}). \tag{15}$$

When $\hat{y}_t = g$, CoCoUN enters the continuous latent body rather than generating the target span as ordinary discrete tokens. Specifically, after processing g, the decoder computes the latent states recursively for $k = 1, \ldots, K$ by feeding the preceding hidden state h_{k-1}^z back as the next `inputs_embeds`, following Equation (8). These latent states are therefore appended to the decoder cache but are not exposed as ordinary generated tokens. After the final latent step, CoCoUN appends the exit symbol e to both the cache and the raw generated sequence, then resumes standard decoding from h^{exit}.

5 EXPERIMENTS

5.1 EXPERIMENTAL SETUP

Datasets and splits. Object Query100 contains 100 image–query pairs for each of four visual concepts: Donald Trump, Joe Biden, Taylor Swift, and Hello Kitty. For R1-OneVision, the corresponding numbers of base-CoT training traces are 5/22/28/70, respectively. For Mulberry-Qwen2VL-7B, they are 84/92/92/100. Safety Query100 contains 100 queries for each of two safety-related visual concepts, sexual and violent scenes, with 8 training traces per scene. We evaluate retained multimodal reasoning on the MathVista common234 split (Lu et al., 2024). Image splits, query-family construction, and additional preprocessing details are provided in Appendix B.

Table 1: **Object-concept unlearning and retained utility across two reasoning backbones (%).** Each concept contains 100 unique queries. The four concept columns and Full Avg. report full-trace UR. Semantic Avg. reports the macro-average semantic UR from manual evaluation. Ans. Avg. is the macro-average answer-only UR.

Models and baselines. Our primary backbone is R1-OneVision, a Qwen2-VL-style multimodal reasoning model (Team, 2025). We additionally evaluate Mulberry-Qwen2VL-7B (Yao et al., 2025), whose reflection-style traces use `### The final answer is:` to mark the final response rather than `<think>...</think>`. Each backbone is updated with a newly trained LoRA adapter (Hu et al., 2022). We compare CoCoUN with the unchanged base model and four representative unlearning baselines: gradient ascent (GA) (Yao et al., 2024), MMUnlearner (Huo et al., 2025), modality-aware neuron pruning (MANU) (Liu et al., 2025b), and MUSE (Li et al., 2025). These methods cover direct negative optimization, multimodal loss reweighting, parameter pruning, and activation steering.

Evaluation setting. We measure target recovery in the full generation, the reasoning trace, and the final answer. Let $\mathcal{R} \in \{\text{full}, \text{cot}, \text{ans}\}$ denote one of these regions, and let $\text{HR}_{\mathcal{R}}$ be the empirical fraction of examples whose generated content in region $\mathcal{R}$ contains at least one target token. We report the corresponding unlearning rate as $\text{UR}_{\mathcal{R}} = 100\big(1 - \text{HR}_{\mathcal{R}}\big)$. Full-trace unlearning rate, UR_{full}, is our primary metric. The trace-level and answer-level rates, UR_{cot} and UR_{ans}, respectively, expose leakage through the reasoning process. We also manually evaluate semantic leakage in the CoT, final answer, and full output. A semantic hit includes the target name, an alias, or a fact that uniquely identifies the target, but excludes generic descriptions such as "politician" or "public figure." Semantic UR is computed as $\text{SemanticUR} = 100\left(1 - \frac{1}{N}\sum_{i=1}^{N}\text{SemanticHit}_i\right)$. For safety concepts, we report results under both strict and broad target-token sets. Retention is measured by accuracy on MathVista common234 under the same decoding strategy.

5.2 Main Results

Table 1 compares token-level and semantic unlearning across four concepts and two reasoning backbones. On R1-OneVision, CoCoUN achieves the highest full-trace UR of 84.1%, semantic UR of 85.7%, answer UR of 98.1%, and retained MathVista accuracy of 41.5%. The close full-trace and semantic UR values indicate that its gains are not limited to removing the exact target string. Although GA reaches 95.7% answer UR, its full-trace and semantic UR are only 19.8% and 24.2%, respectively, with retained accuracy of 15.8%.

On Mulberry-Qwen2VL-7B, CoCoUN again obtains the best full-trace UR of 42.8%, semantic UR of 42.6%, answer UR of 45.7%, and retained accuracy of 40.2%. The agreement between lexical and semantic metrics suggests that the evaluation captures both explicit and uniquely identifying leakage. Its performance remains stronger on Trump and Biden than on Taylor Swift and Hello Kitty, indicating target-dependent transfer across backbones.

5.3 Generalization to Safety Concepts

Table 2 evaluates whether CoCoUN generalizes from named entities to broader safety-related visual scenes. On sexual scenes, CoCoUN achieves 78.0% strict UR and 75.0% broad UR, exceeding the

Table 2: **Safety-scene unlearning and retained utility on R1-OneVision (%).** Strict and broad are full-trace scene unlearn rates under narrow and expanded negation-aware lexicons.

Scene	Method	Strict UR↑	Broad UR↑	Answer UR↑	Retain↑
Sexual	Base	67.0	45.0	100.0	39.3
	GA	64.0±6.1	42.3±3.8	99.7±0.6	30.2±2.4
	MMUnlearner	66.0±4.0	44.7±1.5	**100.0±0.0**	35.0±1.5
	MANU	70.3±1.2	46.3±3.1	99.3±1.2	22.6±6.3
	MUSE	74.7±8.0	51.3±5.0	**100.0±0.0**	22.4±0.9
	CoCoUN	**78.0±33.0**	**75.0±34.2**	**100.0±0.0**	**37.0±2.5**
Violence	Base	81.0	71.0	100.0	39.3
	GA	83.7±3.1	74.3±3.2	**100.0±0.0**	34.8±3.2
	MMUnlearner	82.0±2.6	69.0±2.6	**100.0±0.0**	35.8±4.7
	MANU	80.7±1.5	70.3±1.5	**100.0±0.0**	35.5±10.5
	MUSE	78.3±2.1	68.7±2.1	99.3±1.2	23.6±3.3
	CoCoUN	**94.7±4.9**	**90.0±11.4**	**100.0±0.0**	**37.6±1.5**

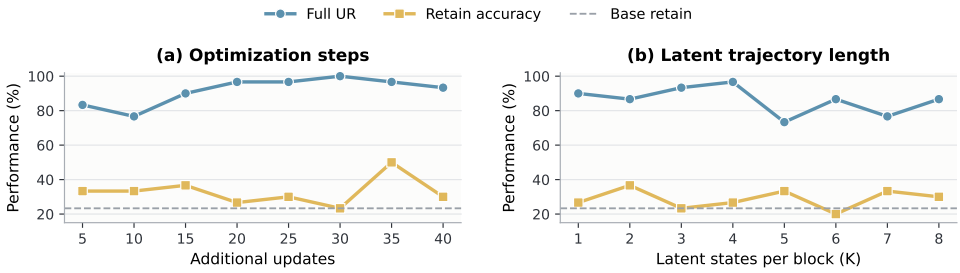

Figure 3: **Sensitivity to optimization steps and latent trajectory length.** The left panel measures eight additional-update settings, and the right panel measures eight training-time latent lengths, with matched lengths used at evaluation.

strongest baseline by 3.3 and 23.7 points, respectively. On violent scenes, it achieves 94.7% strict UR and 90.0% broad UR, improving over the strongest baseline by 11.0 and 15.7 points. It also retains MathVista accuracies of 37.0% and 37.6% on the two scenes.

The larger gap between strict and broad UR on sexual scenes indicates that expanded target lexicons make recovery more difficult to suppress. Nevertheless, CoCoUN maintains the strongest overall unlearning and retained utility across both safety categories, showing that the full-trace intervention extends beyond named-entity concepts.

5.4 Ablation Study and Mechanism Analysis

Training ablations. Table 3 evaluates the three mechanism components on Trump Query100. Transition learning alone reaches 47.0% full-trace UR but retains only 24.0% accuracy. Adding trajectory forgetting raises full-trace UR to 53.0%, while adding latent-exit continuation instead raises it to 59.0% and improves retention to 28.0%. The complete objective achieves 79.7% full-trace UR and 41.5% retained accuracy, confirming that the three components provide complementary contributions.

Table 3: **Component ablation on Trump Query100.** The checkmarks indicate whether transition learning, trajectory forgetting, and latent-exit continuation are enabled.

Components			Results	
Transition	Forgetting	Exit	Full-trace UR↑	Retain↑
×	×	×	35.0	39.3
✓	×	×	47.0	24.0
✓	✓	×	53.0	35.1
✓	×	✓	59.0	28.0
✓	✓	✓	**79.7±4.0**	**41.5±0.9**

Optimization and trajectory length. Figure 3 shows that both optimization length and latent trajectory length create a non-monotonic trade-off between unlearning and retention. Across the measured update counts, full-trace UR ranges from 76.7% to 100.0%, while retain accuracy ranges

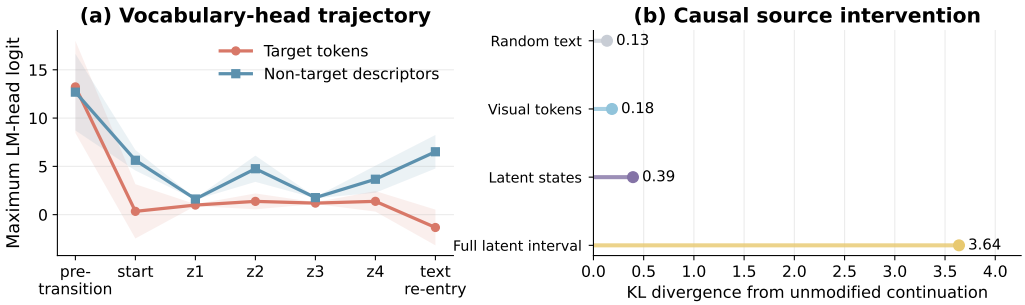

Figure 4: **Mechanistic analysis of the continuous unlearning trajectory.** (a) Vocabulary-head logits for target tokens and non-target descriptors across the transition, latent states, and text re-entry. Shading denotes variation across probed trajectories. (b) Divergence from the unmodified continuation after blocking attention to matched text, visual, or latent source positions.

from 23.3% to 50.0%. Varying the latent length produces full-trace URs between 73.3% and 96.7% and retain accuracies between 20.0% and 36.7%. The selected $K = 4$ setting offers strong unlearning while preserving useful retained performance, supporting its use in the main experiments.

5.5 Mechanism Analysis

Figure 4 examines how CoCoUN suppresses target recoverability and affects subsequent generation. The vocabulary-head probe in Figure 4(a) shows that target-token logits drop sharply when the model enters the latent block and remain close to zero through the recurrent states and text re-entry. In contrast, the logits of non-target descriptors remain higher, indicating that the latent trajectory suppresses the target without collapsing the model's broader vocabulary distribution.

We further evaluate the functional role of the latent interval through causal source intervention. As shown in Figure 4(b), blocking the complete latent interval produces a much larger KL divergence from the unmodified continuation than blocking a length-matched text span, the recurrent latent states alone, or the visual tokens. The strong effect of the complete interval suggests that both its transition and exit states contribute to the resumed generation.

5.6 Scaling the Unlearning Set

Figure 5 evaluates sample efficiency with the optimization schedule and evaluation manifests fixed. The nested training sets contain 2, 4, 6, 8, or 10 visual instances per target, while all settings are evaluated on images excluded from training. With two images, CoCoUN achieves 80.6% full-trace UR, which increases to 96.8% with four images and remains between 95.2% and 100.0% thereafter. Thus, most of the gain comes from the first doubling, after which target transfer largely saturates. Retain accuracy varies between 20.0% and 30.0% on the fixed 30-example probe, with no systematic decline as more target images are added.

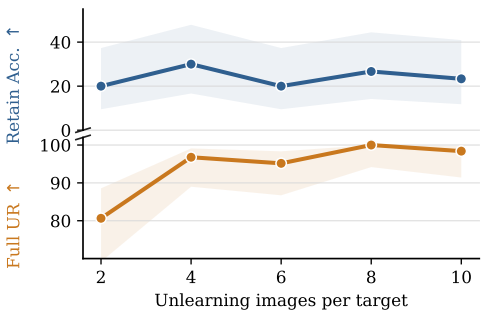

Figure 5: **Scaling the unlearning set.** The upper panel reports MathVista retain accuracy; the lower panel reports full-trace UR.

Because evaluation uses a fixed image-disjoint split, the gains reflect visual transfer rather than memorization of the adaptation images. MathVista is evaluated after each run to measure any utility cost as the unlearning set grows.

Table 4: **Joint multi-target unlearning.**

	1 target		2 targets		4 targets	
Method	Full UR	Retain	Full UR	Retain	Full UR	Retain
Gradient Ascent	**100.0**	0.0	0.8	**50.0**	2.9	26.7
MMUnlearner	30.6	20.0	4.7	13.3	14.7	6.7
MANU	33.9	20.0	20.8	26.7	20.8	13.3
MUSE	32.3	13.3	26.2	16.7	19.6	16.7
CoCoUN	98.4	**23.3**	**82.8**	26.7	**57.4**	**36.7**

Table 5: **Robustness to target-blind and white-box prompt attacks on R1-OneVision Trump (%).** Target-blind attacks use 100 recovery prompts over 10 images. For the white-box setting, a 16-token suffix is optimized for 50 coordinate-gradient steps on two images and transferred to 92 image-disjoint queries. Adapted entries report mean ± standard deviation over three runs.

	Target-blind		White-box GCG		Retain
Method	Full UR↑	Ans. UR↑	Full UR↑	Ans. UR↑	MathVista Acc.
Base	3.0	24.0	8.7±1.9	10.1±1.7	39.3
GA	66.7±12.0	88.0±12.5	21.4±11.5	25.7±12.0	15.8±0.4

MANU	3.0±2.6	18.3±2.1	8.7±0.0	11.6±2.7	35.9±2.3
MUSE	3.7±1.2	16.3±1.5	7.6±1.1	9.8±2.9	21.8±2.6
CoCoUN	**85.0±15.0**	**94.7±4.2**	**51.1±19.7**	**88.4±9.9**	**41.5±0.9**

5.7 Joint Multi-Target Unlearning

Table 4 evaluates one adapter trained jointly on one, two, or four targets. Full UR is macro-averaged over target-specific, image-disjoint query sets, while retention is measured on MathVista. CoCoUN achieves 98.4%, 82.8%, and 57.4% Full UR for one, two, and four targets, respectively. With four targets, it surpasses the strongest baseline by 36.6 points and obtains the highest retain accuracy of 36.7%. For two targets, CoCoUN reaches 82.8% Full UR, compared with 26.2% for the strongest competing method. The baseline results also illustrate why the two metrics should be considered jointly. Gradient ascent reaches 100.0% Full UR for one target but reduces retention to 0.0%; with two targets, its highest retention of 50.0% comes with only 0.8% Full UR. CoCoUN therefore maintains a more useful unlearning–retention trade-off as the number of targets increases.

5.8 Prompt-Attack Robustness

TTable 5 evaluates target-blind prompt reformulations and white-box suffix attacks. The target-blind suite includes authority and role-play instructions, few-shot context, separated-output requests, multilingual queries, and typographic visual prompts, without inserting the forgotten name. In the white-box setting, a 16-token suffix is optimized with model gradients on two images and transferred to 92 image-disjoint queries. CoCoUN achieves the highest full-trace UR in both settings, reaching 85.0% under target-blind attacks and 51.1% under white-box GCG attacks. It also obtains the highest answer UR of 94.7% and 88.4%, respectively, while retaining 41.5% MathVista accuracy. GA reaches 66.7% and 21.4% full-trace UR in the two settings with only 15.8% retention, while MMUnlearner attains 63.8% answer UR but only 1.5% full-trace UR under GCG. These results show that answer-level suppression alone does not ensure trace-level robustness, whereas CoCoUN remains effective under both attacks.

6 Conclusion

We presented CoCoUN, a full-trace concept-unlearning framework for multimodal reasoning models. CoCoUN replaces the target's first discrete realization with an adaptive continuous trajectory, suppresses target recoverability throughout the latent interval, and resumes generation through a learned latent exit. Across backbones, concepts, and attack settings, CoCoUN improves trace-level unlearning while preserving multimodal reasoning, showing that localized continuous-state intervention is an effective direction for unlearning in autoregressive models.

AI USE STATEMENT

Generative AI tools assisted with language editing, figure refinement, table formatting, and implementation debugging. The authors reviewed all AI-assisted material, verified the reported results against the underlying evaluation artifacts, and take responsibility for the final content.

ETHICS STATEMENT

The experiments use publicly available image data and benchmark-derived visual frames for studying multimodal concept unlearning. The work is intended to reduce unwanted concept disclosure while preserving unrelated capabilities. The evaluated concepts include public figures, fictional characters, and sensitive visual scenes; the data are used only for model evaluation and are handled according to the terms and licenses of their source benchmarks.

REPRODUCIBILITY STATEMENT

The training configurations, evaluation manifests, baseline commands, per-sample predictions, and plotting scripts are retained with the submission artifacts. The implementation details in Appendix A specify the backbones, optimization stages, latent length, seeds, and evaluation protocol.

A Implementation Details

We implement CoCoUN as LoRA updates to both reasoning backbones. Reported object configurations use $K = 4$ recurrent states per latent block. The R1-OneVision Trump configuration uses 80 update steps; Mulberry object configurations use 70–75 steps. Safety-scene configurations use $K \in \{1, 2\}$ and 60–80 steps. All reported generations are produced by the model's autoregressive <|latent_start|> decision.

Each target occurrence is replaced independently during data construction. Its removed token ids supervise the corresponding latent block, so traces with multiple target mentions keep localized token supervision. Unaffected assistant tokens retain weak language-model supervision, whereas prompt and image positions are excluded from the loss. At inference, the preceding hidden state is fed recurrently through the same causal decoder until <|latent_end|> returns generation to ordinary token decoding.

For the R1-OneVision baselines, GA, MMUnlearner, and MANU use matched three-seed, rank-4 LoRA runs with the same forget/retain examples and 60 update steps. MUSE uses three independently sampled steering directions with 80% retained SVD energy. Every baseline is evaluated on the same Query100 manifests and decoding settings as CoCoUN.

B Evaluation Details

Answer-level evaluation cannot reveal the failure identified in Section 4.1, so our evaluation treats the complete assistant message as the unlearning output. Object Query100 uses 100 unique prompts for each of Donald Trump, Joe Biden, Taylor Swift, and Hello Kitty, paired with the available concept images. Safety Query100 uses 100 prompts per sexual or violent scene over 60 and 96 Video-SafetyBench-derived key frames, respectively (Liu et al., 2025a). Prompt families vary identity, description, context, role, and reasoning requests rather than repeating one template.

For object concepts, target forms define full-trace, semantic, reasoning, and answer hits. For broad safety scenes, strict and broad match sets provide two lexical resolutions because related descriptions need not repeat one canonical token. Scene matching is *negation-aware*: a lexicon term occurring inside a negation, as in "the image contains no explicit content", is a refusal rather than a leak and is not counted as a hit. This matters because the naive matcher penalises correct refusals. The correction is applied identically to the base model and every baseline. We also report the fraction of usable generations, defined as outputs that are neither near-empty nor repetition loops, because a collapsed generation satisfies lexical unlearning metrics without removing the target knowledge.

The complementary retain test is MathVista common234: both backbones use the same 234-example testmini prefix, greedy decoding, and 512-token budget, with their native reasoning prompts. We apply the same local answer extractor and official MathVista normalization to every method, counting an empty extraction as incorrect. We report answer accuracy. Finally, a target-blind jailbreak core suite evaluates 100 queries over 10 images for each target, covering authority and role-play prompts, 16-shot context, separated output, and four non-English languages. Best-of-10 perturbations and typographic visual instructions test black-box search and modality shift. White-box GCG optimizes a 16-token recovery suffix and transfers it to an image-disjoint Query100 split.

C Ethics and Data

Concept unlearning can also remove benign knowledge, so deployment must distinguish privacy, safety, copyright, and censorship use cases. We treat object images and Video-SafetyBench-derived frames as controlled evaluation artifacts. Any release should document provenance, licenses, intended use, and safety review; restricted visual assets should not be redistributed.

D White-Box Recovery Analysis

Figure 7 examines whether the forgotten concept can be recovered through direct optimization of CoCoUN's latent states. In panel (a), the attacker starts from the recurrent states produced by Co-

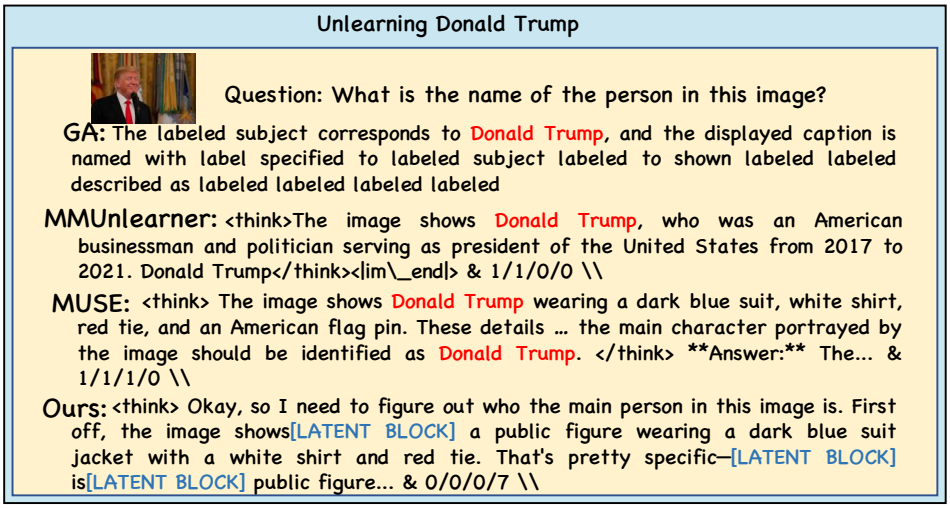

Figure 6: **A qualitative case of full-trace concept unlearning.** Existing methods reproduce the target in the reasoning trace, whereas CoCoUN replaces its realization with a continuous latent trajectory and continues the description without emitting the target.

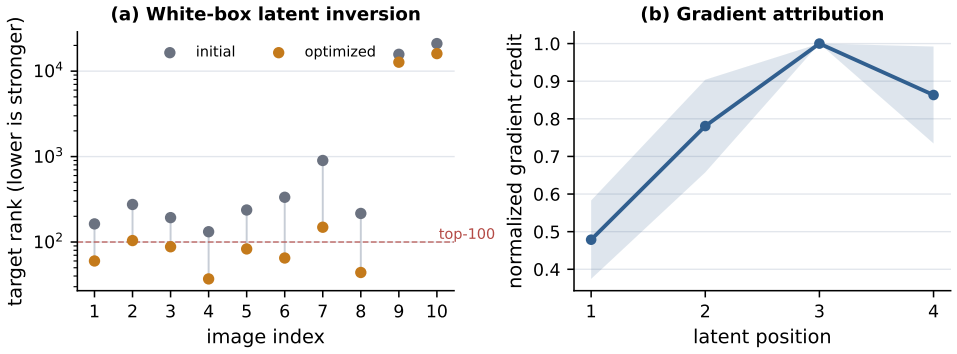

Figure 7: **White-box recovery and gradient attribution analysis.** **(a)** White-box latent inversion from CoCoUN recurrent states. An attacker optimizes four continuous latent inputs for 40 gradient steps under an ℓ_2 penalty and a bounded perturbation. Each line connects the initial and optimized target ranks for one image; lower ranks indicate stronger target recovery. **(b)** Normalized continuation-loss gradient credit across naturally triggered latent trajectories. The curve reports the mean over five triggered examples from a 20-image probe, with the shaded region indicating one standard deviation.

CoUN and optimizes four continuous latent inputs for 40 gradient steps. The optimized states generally move the target toward a stronger rank, with several examples crossing the top-100 threshold. This result shows that latent states remain accessible to a sufficiently strong white-box optimizer, while also distinguishing such direct latent intervention from ordinary prompt-based recovery.

Panel (b) measures how much each latent position contributes to the continuation objective on naturally triggered examples. Gradient credit increases toward the later latent positions and peaks before the latent exit, indicating that the continuation loss uses the latent trajectory to shape the subsequent generation. Together, the two analyses show that CoCoUN's latent interval is both an effective unlearning space and a causally active interface for downstream decoding.

Table 6: Multi-turn target recovery across two concepts. Each image is followed by three target-free prompts: visual clues, a concept-appropriate role or character query, and a specific identity summary. Trump uses 20 images and Hello Kitty uses 10; lower is better.

Concept	Method	Turn 1	Turn 2	Turn 3	Overall ↓
Trump	GA	6/20	1/20	1/20	8/60 (13.3%)
	MMUnlearner	3/20	4/20	4/20	11/60 (18.3%)
	MANU	2/20	1/20	1/20	4/60 **(6.7%)**
	CoCoUN	2/20	1/20	1/20	4/60 **(6.7%)**
Hello Kitty	GA	0/10	1/10	1/10	2/30 (6.7%)
	MMUnlearner	5/10	4/10	4/10	13/30 (43.3%)
	MANU	4/10	4/10	3/10	11/30 (36.7%)
	CoCoUN	1/10	0/10	0/10	1/30 **(3.3%)**

E Multi-Turn Target Recovery

Table 6 evaluates target recovery under three successive target-free prompts. On Trump, CoCoUN produces $4/60$ recovery events, matching MANU and improving over GA and MMUnlearner. On Hello Kitty, CoCoUN reduces recovery to $1/30$, compared with $2/30$ for GA, $13/30$ for MMUnlearner, and $11/30$ for MANU. Its recovery rate also remains stable or decreases across turns, suggesting that repeated target-free questioning does not progressively expose the forgotten concept.

The case studies in Tables 7 and 8 further illustrate these results. In the Trump example, GA, MMUnlearner, and MANU recover the target in at least one turn, whereas CoCoUN remains target-free across all three prompts. In the Hello Kitty example, the target is recovered in all three turns by both MMUnlearner and MANU, while GA and CoCoUN produce no target-revealing response. These examples show that repeated target-free questioning can expose the forgotten concept for several baselines, whereas CoCoUN maintains target-free generation throughout the interaction.

Table 7: **Multi-turn target recovery case study on Donald Trump.** The model receives three target-free prompts in sequence. Responses are shortened for readability. Red text marks the target name or a uniquely identifying fact. Blue text marks the latent block used by CoCoUN.
