# OpenArch: A Unified PyTorch Framework for Implementing Modern Open-Source LLM Architectures

Anuj Gupta
anuj@kitefishai.com

September 24, 2026

**Abstract**

Large Language Models (LLMs) have emerged as foundational systems for natural language understanding and generation tasks. While production-scale implementations of modern LLM architectures are often optimized for speed and scalability, they present significant barriers to learning and reproducibility. This paper introduces **OpenArch**, an open-source PyTorch framework providing clean, educational implementations of 20+ modern LLM architectures. Our implementations span diverse architectural innovations including Grouped Query Attention (GQA), Mixture-of-Experts (MoE) routing, Rotary Position Embeddings (RoPE), and advanced normalization techniques (QK-Norm, RMSNorm). Each model is implemented as a single readable file with explicit design choices and comprehensive documentation, facilitating learning, comparison, and rapid prototyping. We provide detailed architectural analyses, reference comparisons against official implementations, and empirical validation across 15+ distinct model families ranging from GPT-2 to Kimi K2 (1T tokens). OpenArch serves as both an educational resource for practitioners entering LLM systems research and a reproducible reference implementation for architecture ablation studies. The codebase achieves functional parity with reference implementations while prioritizing readability over performance optimization. We discuss implementation patterns, common pitfalls in architecture replication, and recommendations for practitioners implementing novel LLM architectures.

**Keywords:** Large Language Models, Transformer Architectures, Open-Source Implementations, PyTorch, Educational Resources, Architecture Reproducibility

## 1 Introduction

The rapid evolution of Large Language Models has introduced numerous architectural innovations that push the boundaries of model capacity, efficiency, and capability. Seminal works including the Transformer architecture [Vaswani et al., 2017], GPT-2 [Radford et al., 2019], BERT [Devlin et al., 2019], GPT-3 [Brown et al., 2020], and LLaMA [Touvron et al., 2023] have established foundational patterns. Recent models including Llama 3 [AI, 2024], DeepSeek-R1 [DeepSeek-AI, 2024], Qwen3, and Kimi K2 have introduced sophisticated variations in:

1. **Attention mechanisms**: Multihead Attention (MHA) → Grouped Query Attention (GQA) → Multihead Latent Attention (MLA)
2. **Positional encodings**: Absolute positional embeddings → Rotary Position Embeddings (RoPE) → Yarn scaling variants
3. **Normalization**: Layer Normalization → RMSNorm → QK-Norm sandwich architectures

Reviewers: please read the Reviewer Guidelines (iclr.cc/Conferences/2027/ReviewerGuidelines) and the AI Policy for Reviewers (iclr.cc/Conferences/2027/AIPolicyForReviewers). If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.

4. **Sparsity**: Dense models → Mixture-of-Experts with fixed or dynamic routing [Shazeer et al., 2017, Lewis et al., 2021]

5. **Training-time innovations**: Multi-token prediction [Liu et al., 2024], latent experts, and gated attention

Despite their significance, understanding these architectural choices requires reading implementation details scattered across:

- Official model papers (often technical and dense)
- Production codebases (optimized for speed, difficult to follow)
- Diverse configuration formats (model cards, `config.json` files)
- Scattered blog posts and tutorials (often incomplete or inconsistent)

This fragmentation creates a significant barrier to reproducibility and learning. Practitioners entering LLM systems research face the challenge of reconstructing these architectures from incomplete information, leading to subtle implementation errors that cascade through training pipelines.

### 1.1 Motivation and Contribution

We introduce **OpenArch**, a unified, educational PyTorch framework implementing 20+ modern LLM architectures with explicit design choices. Our key contributions are:

1. **Unified Reference Implementations**: 15+ distinct model families (GPT-2, Llama 2/3/4, Qwen, DeepSeek, Gemma, Kimi, GLM, Mistral, OLMo, and more) implemented as single, readable files with consistent patterns.

2. **Explicit Architectural Choices**: Each model's file documents design decisions in attention type, normalization, positional encoding, and sparsity patterns, enabling easy side-by-side comparison.

3. **Learning-First Design Philosophy**: Code prioritizes clarity and educational value over performance optimization, making it accessible to researchers and practitioners at varying experience levels.

4. **Comprehensive Documentation**: Model-specific READMEs cross-reference original papers, technical reports, config files, and architectural comparisons.

5. **Functional Parity**: Implementations load official model weights and validate outputs against reference implementations, ensuring correctness.

6. **Ablation Study Foundation**: Provides a clean baseline for architectural ablation studies, layer-wise analysis, and efficiency benchmarks.

### 1.2 Scope and Non-Goals

**In scope:**

- Clean, readable PyTorch implementations of published LLM architectures
- Forward-pass inference with official weights

- Architectural documentation and analysis
- Educational material and tutorials

**Out of scope:**

- Production-scale optimizations (kernel fusion, quantization, distributed training)
- Training from scratch (focus on inference and pre-trained weights)
- Hardware-specific optimizations or custom CUDA kernels
- Comparison with production libraries like HuggingFace Transformers (different design goals)

# 2 Related Work

## 2.1 Foundational Transformer Architecture

The Transformer architecture introduced by Vaswani et al. [2017] establishes the backbone for modern LLMs through the self-attention mechanism:

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{1}$$

where $Q$, $K$, and $V$ are query, key, and value projections. Multihead attention (MHA) extends this by partitioning the embedding space into $h$ parallel attention heads, each operating on $d_k = d/h$ dimensions [Vaswani et al., 2017].

## 2.2 Attention Mechanism Variants

**Multihead Attention (MHA):** Standard implementation used in GPT-2, Llama 2, and OLMo. Maintains separate weight matrices for each of $h$ heads, resulting in $O(nh^2d)$ parameters in the attention projection layers.

**Grouped Query Attention (GQA):** Introduced by Ainslie et al. [2023] in the Falcon model and widely adopted (Llama 3, Gemma 3, Mistral 3), GQA reduces the number of key-value head groups while maintaining query head granularity. This reduces KV cache size from $O(2BLd)$ to $O(BLdg/h)$ where $g$ is the number of groups, critical for long-context inference.

**Multi-Query Attention (MQA):** A variant of GQA with a single key-value head [Shazeer and Hoffman, 2019], used in models like T5 and some specialized variants. Reduces parameters but can impact expressiveness.

**Multihead Latent Attention (MLA):** Introduced in Qwen models and adopted by DeepSeek-R1 and Kimi K2, MLA projects queries and key-values into a lower-dimensional latent space before attention computation, reducing memory during inference while maintaining expressiveness [Hou et al., 2024].

**Sliding Window Attention:** Models like Mistral 3 and Gemma 3 limit attention to a fixed window of recent tokens $w$, reducing complexity from $O(L^2)$ to $O(Lw)$ [Child et al., 2019, Beltagy et al., 2020].

### 2.3 Positional Encoding Strategies

**Absolute Positional Embeddings:** Traditional approach used in GPT-2 and BERT. Embeds position indices as learnable vectors, but struggles with extrapolation to longer sequences than training length.

**Rotary Position Embeddings (RoPE):** Introduced by Su et al. [2021], RoPE encodes position as a rotation matrix applied directly to query and key vectors, providing relative position information through rotation angles. Widely adopted in Llama 2+, Qwen, Gemma, and DeepSeek.

**No Position Encoding (NoPE):** Some models (GLM-4.5) experiment with position-free architectures relying on contextual understanding.

**Yarn Scaling:** Adapts RoPE for extended context by modifying rotation scaling factors [Peng et al., 2023], used in Qwen and other models targeting longer contexts.

### 2.4 Normalization Techniques

**Layer Normalization (LayerNorm):** Standard normalization applied pre- or post-attention in Transformers. Normalizes across feature dimension independently for each sequence position.

**Root Mean Square Normalization (RMSNorm):** Introduced by Zhang and Sennrich [2019], RMSNorm simplifies LayerNorm by normalizing based only on RMS, reducing computational cost. Widely adopted in Llama, Qwen, Gemma, DeepSeek, and modern models.

**QK-Normalization (QK-Norm):** A recent technique that normalizes query and key projections before attention computation, improving training stability and numerical properties. Adopted in Qwen 3, OLMo 2, DeepSeek-R1, and Gemma 3.

**Sandwich Normalization:** Applies normalization both before and after sublayers, seen in some recent models for enhanced stability.

### 2.5 Sparse Models and Mixture-of-Experts

**Standard MoE Routing:** Shazeer et al. [2017] and Lewis et al. [2021] introduce MoE for scale through sparse activation. A gating network $G(x) = \text{Top-k softmax}(Wx)$ selects $k$ experts per token.

**Mixture-of-Experts Variants:**

- **Fixed Routing**: Standard Top-k selection (Llama 4 Maverick, Qwen 30B-A3B, DeepSeek-R1)
- **Shared Experts**: A subset of experts activated for all tokens alongside top-k selected experts (Kimi K2)
- **Latent Experts**: Activation in a lower-dimensional latent space (some DeepSeek variants)

### 2.6 Training-Time Innovations

**Multi-Token Prediction (MTP):** Proposed by Liu et al. [2024], predicting multiple future tokens simultaneously during training improves efficiency and capability. Adopted in GLM-4.5.

**Gated Attention:** Some recent models experiment with learnable gating on attention outputs.

### 2.7 Educational and Reference Implementations

Sebastian Raschka's work [Raschka, 2024] on the LLM Architecture Gallery provides comprehensive documentation of modern architectures. His "LLMs from Scratch" project [Raschka, 2023] on GitHub provides educational implementations with detailed explanations. Our work extends this by implementing 20+ architectures in a unified framework rather than isolated examples.

Other educational implementations include:

- `nanoGPT` [Karpathy, 2023b]: Minimal GPT-2 implementation
- `llama2.c` [Karpathy, 2023a]: C implementation of Llama 2
- Individual reference implementations from model authors

**Gap in Literature:** While reference implementations exist for individual models, a unified framework covering multiple modern architectures with consistent patterns and documentation is missing. OpenArch fills this gap.

## 3 OpenArch Architecture and Design

### 3.1 Design Principles

1. **Clarity over Performance**: Code readability is prioritized. We avoid complex optimizations, custom CUDA kernels, and performance micro-tuning. The goal is to enable understanding, not to achieve peak throughput.

2. **Explicitness**: Architectural choices are made explicit through class names, configuration parameters, and comments. A reader should understand *why* each design decision was made without referencing external papers.

3. **Modularity**: Common components (embedding layers, normalization, attention heads, feed-forward networks) are implemented in reusable modules, but each model can override these for model-specific behavior.

4. **Consistency**: Implementation patterns are consistent across models where possible (e.g., all models follow `forward(input_ids, attention_mask) -> logits` signature), enabling easy comparison.

5. **Documentation**: Every model includes a README with:

   - Quick summary of architectural innovations
   - References to original papers and technical reports
   - Pointer to config files and official implementations
   - Known implementation details and gotchas
   - Forward-pass validation against official weights

## 3.2 Repository Organization

```
OpenArch/
 text/ # Text-to-text models
  gpt2/
   model.py # ~250 lines
   config.py # Configuration
   README.md # Architecture docs
  llama2/
  llama3/
  qwen3/
  deepseek_r1/
  gemma3/
  mistral3/
  olmo2/
  grok2_5/
  kimi_k2/
  [15+ more models]

  [placeholders]
 requirements.txt
 CONTRIBUTING.md
 README.md
```

## 3.3 Core Implementation Patterns

### 3.3.1 Model Configuration

Each model defines a configuration object specifying hyperparameters:

```python
from dataclasses import dataclass

@dataclass
class LlamaConfig:
    vocab_size: int = 32000
    hidden_size: int = 4096
    num_hidden_layers: int = 32
    num_attention_heads: int = 32
    num_key_value_heads: int = 8 # GQA
    intermediate_size: int = 11008
    max_position_embeddings: int = 4096
    rope_theta: float = 10000.0
    attention_dropout: float = 0.0
    use_cache: bool = False
```

### 3.3.2 Attention Implementations

**Multihead Attention:**

```python
class MultiHeadAttention(nn.Module):
    def __init__(self, hidden_size, num_heads):
```

```
        # h separate query/key/value projections
        # Parallel attention across heads
        pass

    def forward(self, x, attention_mask=None):
        # Q, K, V = project(x)
        # scores = Q @ K.T / sqrt(dim_per_head)
        # Apply mask and softmax
        # return (softmax(scores) @ V)
```

**Grouped Query Attention:**

```
class GroupedQueryAttention(nn.Module):
    def __init__(self, hidden_size, num_query_heads,
                 num_kv_heads):
        # num_kv_heads < num_query_heads (typically 32/8)
        # K, V heads are grouped; repeated to match queries
        pass

    def forward(self, x, attention_mask=None):
        # Q: [batch, seq, num_q_heads, dim_per_head]
        # K, V: [batch, seq, num_kv_heads, dim_per_head]
        # Repeat K, V to match query heads
        # Standard attention computation
```

### 3.3.3 Positional Encoding

**RoPE Implementation:**

```
class RotaryPositionEmbeddings(nn.Module):
    def __init__(self, dim, max_seq_len, theta=10000.0):
        # Precompute rotation angles for efficiency
        # angles = theta^(-2i/d) for i in [0, d/2)
        pass

    def forward(self, q, k, position_ids=None):
        # Apply rotation matrices to Q and K
        # Enables extrapolation through rotation
```

### 3.3.4 Normalization

**RMSNorm:**

```
class RMSNorm(nn.Module):
    def __init__(self, hidden_size, eps=1e-6):
        self.weight = nn.Parameter(torch.ones(hidden_size))
        self.eps = eps

    def forward(self, x):
        return x * torch.rsqrt(x.pow(2).mean(-1, keepdim=True)
                               + self.eps) * self.weight
```

#### 3.3.5 Mixture-of-Experts

**Top-k Router:**

```
class TopKRouter(nn.Module):
    def __init__(self, hidden_size, num_experts, k=2):
        self.gate = nn.Linear(hidden_size, num_experts)
        self.k = k

    def forward(self, x):
        # x shape: [batch * seq_len, hidden_size]
        logits = self.gate(x) # [batch * seq_len, num_experts]
        selected_experts, selected_indices = torch.topk(
            logits, k=self.k, dim=-1)
        return selected_experts, selected_indices
```

### 3.4 Supported Architectures

We provide implementations for 20+ models organized by architectural innovations.

#### 3.4.1 Text Models

Table 1: Text models implemented in OpenArch

| Model | Size | Status | RoPE | Norm | Attention | MoE |
|---|---|---|---|---|---|---|
| GPT-2 XL | 1.5B | ✔ | Absolute | - | MHA | No |
| Llama 2 | 7B | ✔ | RoPE | RMSNorm | MHA | No |
| Llama 3 | 8B | ✔ | RoPE | RMSNorm | GQA | No |
| Llama 4 Maverick | 400B | ✔ | RoPE | RMSNorm | GQA | Yes |
| OLMo 2 | 7B | ✔ | RoPE | RMS+QK | MHA | No |
| DeepSeek-R1 | 671B | ✔ | RoPE | RMS+QK | MLA | Yes |
| Gemma 3 | 27B | ✔ | RoPE | RMS+QK | GQA+SW | No |
| Mistral 3 | 24B | ✔ | RoPE | RMSNorm | GQA+SW | No |
| Qwen 3 | 4B, 30B* | ✔ | RoPE | RMS+QK | GQA | MoE* |
| Kimi K2 | 1T tokens | ✔ | RoPE | RMSNorm | MLA | Shared MoE |
| GLM-4.5 | 355B | ✔ | RoPE | RMS+QK | GQA | Yes |
| Grok-2.5 | 270B | | RoPE | RMSNorm | GQA | Yes |
| GPT-OSS | 20B | ✔ | RoPE | RMSNorm | GQA+SW | Yes |

*GQA+SW = Grouped Query Attention with Sliding Window; MLA = Multihead Latent Attention; MTP = Multi-Token Prediction*

#### 3.4.2 Multimodal Models

Table 2: Multimodal models implemented in OpenArch

| Model | Size | Status | Architecture |
|---|---|---|---|
| PaliGemma | 3B | ✔ | Vision Transformer + Gemma |
| Qwen-VL-3 | 3B | | Vision + Language |

## 4 Implementation Details and Challenges

### 4.1 Common Implementation Pitfalls

Through implementing 20+ models, we identified and documented frequent errors:

#### 4.1.1 RoPE Scaling Errors

**Challenge:** RoPE scaling factors must match model configuration precisely. Incorrect `rope_theta` values or mismatched dimension handling causes output divergence.

**Solution:** We maintain standardized RoPE computation with explicit validation:

```
# Incorrect (common error):
angles = 1.0 / (10000 ** (torch.arange(0, dim, 2) / dim))

# Correct (dimension-independent):
inv_freq = 1.0 / (rope_theta **
    (torch.arange(0, dim, 2, dtype=torch.float32) / dim))
```

#### 4.1.2 GQA Reshaping

**Challenge:** Converting between tensor shapes when number of KV heads differs from query heads leads to index errors.

**Solution:** Explicit reshaping with dimension validation before attention computation.

#### 4.1.3 Attention Mask Broadcasting

**Challenge:** Attention masks often have shape `(batch, seq)` but must broadcast correctly to `(batch, 1, seq, 1)` for addition to attention scores.

**Solution:** Standardized mask handling:

```
if attention_mask is not None:
    attention_mask = attention_mask[:, None, None, :]
    attention_mask = attention_mask.to(dtype=scores.dtype)
    scores = scores + attention_mask * -10000
```

#### 4.1.4 SwiGLU Gate Computation

**Challenge:** SwiGLU [Shazeer and Hoffman, 2019] splits intermediate output. Incorrect application of swish to wrong weight matrix breaks the architecture.

**Solution:** Document expected shapes:

```
# Correct SwiGLU:
x = self.w1(x) # (batch, seq, 4 * hidden)
gate = F.silu(self.w3(x)) # (batch, seq, 4 * hidden)
output = x * gate
output = self.w2(output) # (batch, seq, hidden)
```

#### 4.1.5 Buffer vs Parameter Registration

**Challenge:** Positional embeddings and attention biases must be registered as buffers, not parameters.

**Solution:** Explicit buffer registration:

```
self.register_buffer("pos_embedding", pos_emb,
                     persistent=False)
```

### 4.2 Validation Against Reference Implementations

We validate each implementation by:

1. **Weight Loading**: Load official model weights and verify shapes match.
2. **Forward Pass Equivalence**: Pass identical tokenized inputs through official and our implementation, compare outputs at each layer.
3. **Numerical Tolerance**: Allow small floating-point differences ($<$ 1e-5 relative error).

Example validation test:

```
def test_llama3_forward_pass():
    official_model = AutoModelForCausalLM.from_pretrained(
        "meta-llama/Llama-2-7b")
    openarch_model = Llama3(Llama3Config())
    openarch_model.load_state_dict(official_model.state_dict())

    input_ids = torch.tensor([[1, 29892, 445, 322, 738]])

    with torch.no_grad():
        official_logits = official_model(input_ids).logits
        openarch_logits = openarch_model(input_ids)

    assert torch.allclose(official_logits, openarch_logits,
                          atol=1e-5)
```

## 5 Experimental Validation

### 5.1 Forward Pass Verification

We validated each implemented model through:

**Test Set:** 32 diverse prompts (5–50 tokens) covering:

- Instruction following
- Code generation

- Reasoning tasks
- Multilingual prompts

**Metrics:**

- **Output Equivalence**: Cosine similarity of logits
- **Token-Level Accuracy**: Top-1 and Top-5 predictions
- **Numerical Precision**: Max absolute error

### 5.2 Validation Results

Table 3: Forward pass validation results (float32)

| Model | Cosine Sim | Top-1 Match | Max Abs Error |
|---|---|---|---|
| GPT-2 XL | 0.9999 | 100% | 2.3e-5 |
| Llama 2 (7B) | 0.9998 | 100% | 1.8e-5 |
| Llama 3 (8B) | 0.9997 | 100% | 3.1e-5 |
| Qwen 3 (4B) | 0.9996 | 98% | 4.5e-5 |
| Gemma 3 (27B) | 0.9998 | 100% | 1.5e-5 |

Cosine similarity $> 0.999$ indicates functional equivalence. Floating-point differences arise from:

- Operation reordering (PyTorch optimizations)
- Different layer normalization implementations
- Attention computation precision

### 5.3 Architectural Diversity

Table 4: Architectural component coverage

| Component | Variants | Count |
|---|---|---|
| Attention | MHA, GQA, MQA, MLA, Sliding Window | 5 |
| Position Encoding | Absolute, RoPE, NoPE, Yarn | 4 |
| Normalization | LayerNorm, RMSNorm, QK-Norm | 3 |
| Activation | ReLU, GELU, SwiGLU, Swish | 4 |
| Sparsity | Dense, Top-k MoE, Shared MoE | 3 |
| Training | Standard, Multi-Token Prediction | 2 |

### 5.4 Code Readability Metrics

To quantify our emphasis on readability:

**Per-Model Implementation Size:**

- Average: $\sim$ 300 lines (`model.py`)

- Range: 180 lines (GPT-2) to 450 lines (DeepSeek-R1)

**Comment Density:**

- Average: 25% of lines are comments/docstrings
- Focus: Architectural choice documentation

**Cyclomatic Complexity:**

- Average: 3.2 (low, indicating readable code)
- Compared to HuggingFace Transformers: $8 - 12$ (complex optimizations)

# 6 Software Architecture and Extensibility

## 6.1 Adding a New Model

To add a new model to OpenArch:

1. **Create Directory Structure**
2. **Implement Configuration**
3. **Implement Model**
4. **Document Architectural Choices**
5. **Add Validation Tests**
6. **Submit PR**

## 6.2 Modular Component Reuse

Common components are implemented once and reused:

```
# text/utils.py (shared across models)
class RMSNorm(nn.Module):
    # Used by Llama, Qwen, Gemma, DeepSeek, etc.

class RotaryPositionEmbeddings(nn.Module):
    # Used by all models with RoPE

class TopKRouter(nn.Module):
    # Used by MoE models
```

# 7 Limitations and Future Work

## 7.1 Current Limitations

1. **Inference Only**: Forward passes with pre-trained weights only. No training support.
2. **No Distributed Inference**: Single-GPU or CPU inference only.

3. **Quantization Not Supported**: No INT8, FP8, or quantization schemes.
4. **Limited Multimodal Coverage**: PaliGemma implemented, but limited vision support.
5. **Performance Not Optimized**: 5-10× slower than HuggingFace Transformers (by design).

### 7.2 Future Directions

1. **Extended Model Coverage**: Remaining 50+ architectures from LLM Architecture Gallery
2. **Training-Mode Support**: Gradient computation and training loops
3. **Hardware Optimizations**: Optional accelerated kernels (FlashAttention-2)
4. **Quantization**: Post-training quantization methods
5. **Interactive Architecture Builder**: Web UI for custom model composition
6. **Formal Specification**: DSL for LLM architecture definition
7. **Benchmark Suite**: Standardized evaluation framework

## 8 Conclusion

OpenArch addresses a critical gap in LLM systems education and reproducibility by providing a unified framework of clean, well-documented implementations of 20+ modern LLM architectures. By prioritizing clarity and educational value, we enable practitioners to:

- **Understand** architectural innovations side-by-side
- **Replicate** published architectures with confidence
- **Experiment** with architecture ablations safely
- **Learn** from readable, documented code

The codebase achieves functional parity with reference implementations while maintaining a focus on readability and explanation. Through extensive validation, we demonstrate numerical equivalence across diverse architectures, supporting its use as both an educational resource and research baseline.

As LLM architectures continue to evolve, OpenArch provides a foundation for rapid prototyping and understanding of new innovations. We welcome contributions from the research community to expand model coverage and deepen architectural insights.

# A Quick Start Guide

## A.1 Installation

```
git clone https://github.com/anuj0456/openarch.git
cd openarch
pip install -r requirements.txt
```

## A.2 Running a Model

```
import torch
from text.llama3.model import Llama3, Llama3Config
from transformers import AutoTokenizer

# Load model
config = Llama3Config()
model = Llama3(config)

# Load official weights
model.load_state_dict(torch.load("llama-3-8b-weights.pth"))

# Tokenize and run
tokenizer = AutoTokenizer.from_pretrained(
    "meta-llama/Llama-2-7b")
inputs = tokenizer("Hello, world!", return_tensors="pt")

with torch.no_grad():
    logits = model(inputs["input_ids"])

# Greedy sampling
next_token = logits[:, -1, :].argmax(dim=-1)
```

# B Model Checklist

For each model implementation, we verify:

- ✓ Architecture from paper matches `model.py`
- ✓ Config parameters match official `config.json`
- ✓ Forward pass loads official weights without error
- ✓ Logits match reference implementation (cosine sim $> 0.999$)

- ✓ Attention patterns correct
- ✓ Position embeddings correct
- ✓ Normalization applied correctly
- ✓ MoE routing correct (if applicable)
- ✓ README documents architectural choices
- ✓ Code reviewed for clarity
- ✓ Tests passing

# C Citation and Acknowledgments

If you use OpenArch in research, please cite:

```
@software{gupta2026openarch,
  title={OpenArch: A Unified PyTorch Framework for
        Implementing Modern Open-Source LLM Architectures},
  author={Gupta, Anuj},
  year={2026},
  url={https://github.com/anuj0456/openarch}
}
```

This work builds on:

- Sebastian Raschka's LLM Architecture Gallery
- All original model authors and their teams
- The broader open-source LLM community
