BEYOND ISOLATED CULTURES: CULTURAL-SPHERE PRIORS IMPROVE CULTURAL CHARACTERIZATION AND NARROW LOW-RESOURCE ALIGNMENT GAPS

Anonymous authors
Paper under double-blind review

ABSTRACT

Aligning LLMs with diverse cultural values is essential for their global deployment. Human cultures exhibit structured relationships that capture value similarities and differences, shaping cultural-sphere structure. However, existing methods primarily treat cultures as isolated targets, leaving these relationships largely underused. To bridge this gap, we investigate *whether cultural-sphere structure can serve as a relational prior for cultural alignment*. Across 10 models and 3 complementary benchmarks, sphere-aware prompting consistently outperforms culture-only baselines, with particularly large gains for low-resource cultures. It recovers more human-like cultural structure. To identify the source of improvement, we ablate the prompt and find agreement among same-sphere cultures as the strongest effective signal, with larger gains on questions exhibiting greater within-sphere consensus. We further study its effectiveness on target cultures where data is unavailable. Using within-sphere consensus as proxy supervision, sphere-aware fine-tuning substantially improves alignment on held-out cultures and generalizes to an unseen benchmark. Overall, the results support cultural-sphere relations as a useful prior for alignment across both prompting and fine-tuning.

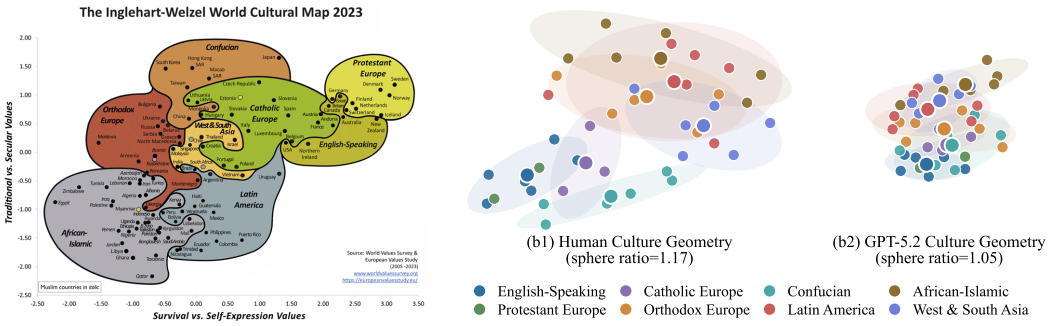
1 INTRODUCTION

Large language models (LLMs) are increasingly deployed in diverse cultural contexts, where values and opinions vary across societies (Inglehart & Baker, 2000; Hofstede, 2001). However, their responses often disproportionately reflect Western and English-speaking perspectives, failing to capture the diversity of values held by their users (Durmus et al., 2024; Myung et al., 2024; Naous et al., 2024). This mismatch is particularly concerning for cultures underrepresented in model training data (Joshi et al., 2020; Dodge et al., 2021; Kazemi et al., 2024). Therefore, aligning LLMs with diverse cultural values is critical for their global deployment (Ouyang et al., 2022).

Existing methods improve cultural alignment through two main paradigms: (i) prompting LLMs with value profiles of a target culture (Cao et al., 2023; Tao et al., 2024; AlKhamissi et al., 2024) and (ii) fine-tuning LLMs on culture-specific value data (Li et al., 2024a;b; Xu et al., 2025; Yao et al., 2026). Despite their effectiveness, both paradigms organize alignment around individual target cultures, without explicitly modeling how cultures relate to one another (Adilazuarda et al., 2024). *Consequently, the relationships among cultures remain largely underused as an explicit signal for improving cultural alignment.*

Real human cultures are neither interchangeable nor entirely independent, instead, their values exhibit structured similarities and differences (Ronen & Shenkar, 2013; Muthukrishna et al., 2020). The Inglehart–Welzel World Cultural Map (Inglehart & Welzel, 2005; World Values Survey, 2023) organizes countries into broader cultural spheres along two value dimensions (shown in Figure 1 (a)). Consistently, our analysis of human survey responses finds systematically higher similarity within spheres than across spheres, producing a similar sphere organization in the visual geometry (Figure 1 (b1)). Consequently, modeling this relational structure may benefit cultural alignment in two complementary ways. *First, it enables a more informative relational characterization of each target culture.* Beyond its own observed attributes, a culture can be characterized through its position relative to others, including which cultural patterns provide relevant similarities and which provide

Reviewers: please read the Reviewer Guidelines (iclr.cc/Conferences/2027/ReviewerGuidelines) and the AI Policy for Reviewers (iclr.cc/Conferences/2027/AIPolicyForReviewers). If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.



(a) Inglehart–Welzel World Cultural Map

(b) Human vs. GPT-5.2 Culture Geometry

Figure 1: **(a)** The Inglehart–Welzel World Cultural Map defines our sphere prior (source: World Values Survey[2]). **(b)** A joint 2D MDS embedding compares **(b1)** human WVS profiles with **(b2)** GPT-5.2 profiles under culture-only prompting. Human profiles show clearer sphere separation and a higher within-to-between similarity ratio (1.17 vs. 1.05).

informative contrasts. *Second, the structure guides transfer when target-specific data is scarce.* For cultures underrepresented in pretraining or alignment data, related cultures may provide otherwise unavailable reference information (Sun et al., 2021), helping alleviate the resulting cold-start problem (Schein et al., 2002).

However, this relational structure does not necessarily emerge from alignment with individual target cultures. As an initial diagnostic, Figure 1 (b2) shows that GPT-5.2 profiles under culture-only prompting exhibit weaker sphere differentiation and a more compressed cultural geometry than human profiles. To bridge this gap, we investigate *whether cultural-sphere structure can serve as an explicit relational prior to improve cultural alignment through three research questions*. **RQ1: Can cultural-sphere structure improve prompting-based cultural alignment? (§4)** Across ten LLMs and three complementary benchmarks, we find that sphere-aware prompting consistently improves cultural alignment, and gains increase as more sphere information is provided in the prompt. Large gains are observed on low-resource cultures, reducing disparities in cultural alignment. **RQ2: How does cultural-sphere structure improve cultural alignment? (§5)** Sphere-aware prompting recovers a more human-like relational structure than culture-only prompting. Prompt ablations further indicate that agreement among same-sphere cultures provides the strongest effective signal. The gains are larger on questions with greater within-sphere consensus and for the low-resource cultures examined in our study. **RQ3: Can cultural-sphere structure support alignment when target-culture data is unavailable? (§6)** We study a cultural cold-start setting in which no training labels are available for the target culture. Using within-sphere consensus as proxy supervision, sphere-based fine-tuning rivals an oracle trained on those cultures' own labels, and the resulting alignment transfers to another unseen benchmark.

In summary, our contributions are three-fold. (1) We formulate cultural alignment from a relational perspective, identify a structural gap between existing cultural alignment and the organization of real human cultures, and introduce cultural spheres as an explicit relational prior for improvement. (2) Across ten LLMs and three benchmarks, we demonstrate the effectiveness of cultural-sphere prior and identify within-sphere consensus as the primary gain source. (3) We propose a cultural-sphere-grounded proxy supervision strategy for cultures without target-specific data, showing that signals from culturally close neighbours can improve alignment on held-out low-resource cultures.

2 Related Work

Cultural bias in LLMs. Cross-cultural evaluations have shown that LLM outputs are biased toward particular cultural groups (Adilazuarda et al., 2024), with research along three lines. First, studies of values and opinions find that model responses disproportionately reflect Western and English-speaking populations (Johnson et al., 2022; Arora et al., 2023; Tao et al., 2024; Durmus

[2]Reprinted from the Inglehart–Welzel World Cultural Map (World Values Survey, 2023).

et al., 2024; Cao et al., 2023; Wang et al., 2024; Zhao et al., 2024), while standard alignment may further reduce perspective diversity (Ryan et al., 2024). Second, cross-cultural adaptability studies find larger errors for underrepresented groups and Global South cultures (Naous et al., 2024; AlKhamissi et al., 2024; Rao et al., 2025). Third, cultural knowledge benchmarks show weaker performance on cultures underrepresented online (Myung et al., 2024; Chiu et al., 2025). These findings establish systematic cultural bias in LLMs, underscoring the need for cultural alignment.

Cultural alignment methods. Existing cultural alignment methods follow two paradigms. *Prompt-based approaches* provide LLMs with cultural context such as country names, personas or value descriptions, relying on knowledge already encoded in the model (Tao et al., 2024; Cao et al., 2023; AlKhamissi et al., 2024; Choenni & Shutova, 2024; Wang et al., 2025). *Tuning-based approaches* fine-tune models with culture-specific supervision, using supervised objectives (Li et al., 2024a; Xu et al., 2025) or culturally grounded reinforcement learning (Zhao et al., 2026); some methods additionally expand the training data through synthetic augmentation (Li et al., 2024b; Liu et al., 2025; Yao et al., 2026). However, both paradigms treat each culture as an independent alignment target, leaving cross-cultural relationships largely unexploited as an alignment signal. Prompting lacks a principled mechanism for incorporating culturally related references, while tuning requires target-culture labels often scarce for the low-resource cultures most in need of alignment (Li et al., 2024a; Xu et al., 2025). This paper instead introduces cultural-sphere structure as an explicit relational prior for cultural alignment. We use same-sphere evidence to guide prompting toward shared cultural patterns and apply sphere consensus as proxy supervision for low-resource cultures in fine-tuning.

3 Problem Setup and Cultural-Sphere Prior

3.1 Formulation of Cultural Alignment

Let $c \in \mathcal{C}$ denote a culture (a country or region in our setting), $q \in \mathcal{Q}_c$ a question, and $p_c^\star(y \mid q)$ denote the human response distribution for culture c. Given an LLM p_θ, a cultural alignment method ω either specifies a culture-conditioned prompt T_ω or updates the model parameters to θ_ω. Both seek to minimize the discrepancy between the human and model response distributions.

$$\min_{\omega} \; \mathbb{E}_{c\sim\mathcal{C},\, q\sim\mathcal{Q}_c} \mathcal{D}(p_c^\star(\cdot \mid q), p_\theta^\omega(\cdot \mid q)) \,. \tag{1}$$

3.2 Benchmarks for Training and Evaluation

We adopt three complementary cultural benchmarks spanning closed-ended surveys and open-ended responses. **(1) World Values Survey (WVS)** (Haerpfer et al., 2022): from the original data, we retain 41 countries and regions with 149 survey questions. Alignment is the fraction of questions for which the model's answer $\hat{a}_\theta(q, c)$ matches the dominant human response $y_{c,q}$: $\mathrm{Acc}_c = \frac{1}{|\mathcal{Q}_c|} \sum_{q\in\mathcal{Q}_c} \mathbb{I}[\hat{a}_\theta(q, c) = y_{c,q}]$. **(2) Hofstede Values Survey Module (VSM)** (Hofstede & Minkov, 2013) covers 37 countries with 24 Likert items mapped to six cultural dimensions. Alignment is measured as the normalized similarity between model-derived dimension scores $r_{\theta,c}$ and published Hofstede country scores $r_c^\star$: $\mathrm{Sim}_c = 1 - \frac{\|r_c^\star - r_{\theta,c}\|_2}{(100\sqrt{6})}$. **(3) PRISM** (Kirk et al., 2024) provides open-ended evaluation on a subset of 626 value-guided prompts across 13 countries. A reference-calibrated LLM judge J_ϕ scores alignment: $\mathrm{Score}_c = \frac{1}{|\mathcal{Q}_c|} \sum_{q\in\mathcal{Q}_c} J_\phi(q, c, \hat{y}_\omega(q, c))$. All reported results are culture-level macro-averages.

For fine-tuning (Section 6), WVS provides the sole supervision for generating training data via CulturePark (Li et al., 2024b). WVS evaluation and training seed questions are disjoint. VSM and PRISM are reserved for evaluation only. Full metric definitions and dataset details are in Appendices B and C.

3.3 Cultural-Sphere Prior

Cultural spheres provide a relational structure that identifies cultures with similar or contrasting value patterns (Inglehart & Baker, 2000). In this paper, we adopt the eight spheres of the Inglehart–Welzel World Cultural Map (Figure 1(a)), a widely used framework grounded in decades of World

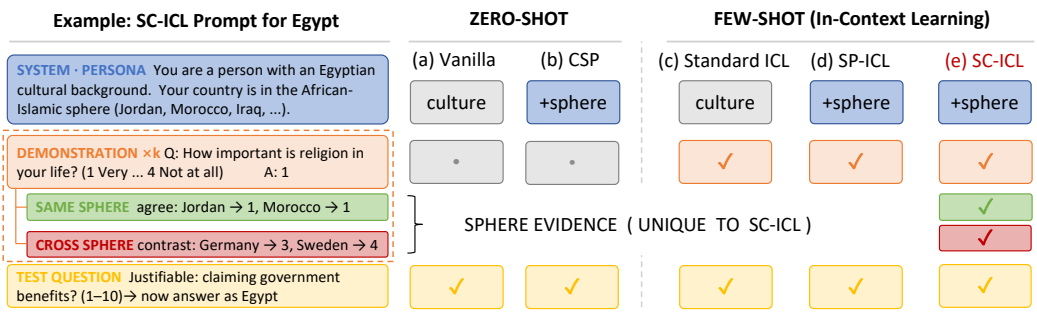


Figure 2: Overview of zero-shot and few-shot prompting methods for cultural-sphere alignment.

Values Survey research (World Values Survey, 2023). Let $\mathcal{S}$ denote the set of spheres, $s(c) \in \mathcal{S}$ the sphere assigned to culture c, and $\mathcal{C}_s = \{c \in \mathcal{C} : s(c) = s\}$ its member cultures.

We test whether these spheres capture structure in our data. In both WVS and Hofstede 6-D values, all eight spheres show greater similarity within spheres than across spheres (mean ratios are $1.172 > 1$ and $1.167 > 1$, respectively). Clustering without sphere labels at k=8 yields adjusted Rand indices (ARI) of 0.245 and 0.420 against the sphere assignments. Both exceed the corresponding 97.5th-percentile permutation baselines (0.077 and 0.081; p_{perm}=0.0001), confirming that the groupings capture structure in the data (Appendix D). We use the Inglehart–Welzel spheres as one instantiation, while our methods apply to updated sphere assignments as cultural boundaries evolve.

4 Can Cultural-Sphere Structure Improve Prompting-Based Cultural Alignment?

Since advanced LLMs already encode rich cultural knowledge, as evidenced by the effectiveness of prompt-based cultural alignment, we ask whether explicitly appending cultural-sphere information to the prompt improves alignment. We evaluate this intervention on survey-based and open-ended benchmarks, across a broad selection of ten mainstream LLMs from five developers, ranging from open-weight models across scales to proprietary general-purpose and reasoning systems.

4.1 Experiment Details

Figure 2 shows the two prompting settings. In the *zero-shot* setting, **Culture-only (Vanilla)** specifies only the target culture (e.g., "You are a real person with an Egyptian cultural background"), while **Cultural-Sphere Prompt (CSP)** adds the target culture's sphere and peer cultures to the prompt.

The *few-shot* setting adds in-context demonstrations.[3] For each test question, all variants retrieve identical demonstrations from a held-out pool using deterministic BM25, without exposing its gold answer or response distribution. They differ only in accompanying information. **Standard ICL** pairs the demonstrations with the culture-only prompt, whereas **Sphere-Prompted ICL (SP-ICL)** replaces it with CSP. **Sphere-Contrastive ICL (SC-ICL)** further augments each demonstration with reference answers from same-sphere cultures and contrasting answers from a distant sphere. Full prompt templates are in Appendix E.

4.2 Overall Results

Cultural-sphere priors improve alignment. Table 1 supports two findings. (1) *Sphere-aware prompting consistently improves alignment across evaluation benchmarks*, raising VSM normalized similarity by $+3.7\%$ and PRISM judge scores by $+3.3\%$. *The gains hold across model families and scales*, from proprietary systems (GPT-5, o3) to open-weight models (DeepSeek-V3.2, Mistral-Large-3, Llama-3.3-70B). (2) *Alignment gains increase as prompts provide richer, finer-grained*

[3] We limit this setting to WVS because VSM and PRISM lack enough comparable samples for ICL demonstrations.

Table 1: Prompting-based cultural alignment results. See Section 3.2 for benchmark and metric definitions. Parentheses: model-level relative gain over Vanilla, $100\,(\text{score} - \text{Vanilla})/\text{Vanilla}$; 95% CI: uncorrected t-based interval over the ten model-level gains. **Bold** marks the best result per model and benchmark. Appendix H.1 reports culture-level bootstrap intervals.

cultural signals. On WVS, zero-shot CSP yields a modest gain, while plain few-shot demonstrations do not reliably help. Adding the sphere description provides a marginal gain, whereas pairing same-sphere evidence with a distant-sphere contrast produces a substantially larger gain ($+12.1\%$) and ranks best for every model. *This progression confirms that richer cultural signals consistently improve alignment, with the full relational contrast providing the largest gains.*

Sphere-level patterns. As shown in Table 2, *the cultural-sphere prior narrows cross-sphere disparity in cultural alignment, with larger gains for spheres that perform weaker at baseline*. On WVS, English-Speaking and Protestant Europe lead under Vanilla, consistent with LLMs' known Western skew (Tao et al., 2024; Durmus et al., 2024), while sphere-contrastive prompting benefits lower-performing spheres most: African-Islamic and West & South Asia gain $+16.9\%$ and $+15.0\%$, three to four times Protestant Europe's gain ($+4.7\%$). This suggests that relational cues compensate more where models have less cultural knowledge. Across the three benchmarks, sphere-aware prompting lowers cross-sphere CV, mitigating disparities from uneven pretraining.

5 How Does Cultural-Sphere Structure Improve Cultural Alignment?

As discussed in Section 1, cultural-sphere structure may benefit cultural alignment by enabling a relational characterization of each target culture and promoting knowledge transfer to low-resource cultures. In this section, we examine how it helps alignment by asking (i) *whether it recovers more human-like relationships among cultures*, (ii) *which structural cues in the prompt are effective and on which questions they help most*, and (iii) *whether the gains are larger for lower-resource cultures*.

5.1 Cultural Structure Analysis

We first investigate whether sphere-aware prompting recovers more human-like cultural structure.

Experimental details. For each method, we compute a culture–culture similarity matrix from model responses and compare it with the human reference using two structural metrics. (1) The **Within/Between ratio** compares mean similarity within and across spheres. We also report its absolute gap (Δ) from the human ratio. Smaller values are better. (2) ρ_{HM} is the Spearman correlation between the model and human matrices. Higher values indicate closer agreement with the human ranking of culture pairs. See Appendix F.2 for definitions and Appendix H.3 for per-model tables.

Result analysis. As shown in Table 3, sphere-aware prompting recovers more human-like cultural structure across both benchmarks and metrics. On WVS, sphere-contrastive prompting (SC-ICL) raises ρ_{HM} from 0.474 to 0.690, while on VSM, the cultural-sphere prompt alone (CSP) raises it from 0.236 to 0.381. Across both benchmarks, agreement shifts from weak or moderate to substantial overlap with human cultural-distance rankings. Figure 3 shows that Vanilla flattens cultural distinctions into a near-uniform similarity matrix, while sphere-aware prompts restore the human within-sphere block structure. Consequently, the sphere prior improves per-culture alignment and recovers the relational geometry compressed by culture-only prompting.

Table 3: Model-averaged human–model structural similarity. Bold marks the smallest Δ and highest ρ_{HM}.

Data	Method	Within/Between [$\Delta \downarrow$]	$\rho_{\mathrm{HM}} \uparrow$
WVS	**Human**	1.172	1.000
	Vanilla	1.079 [Δ0.093]	0.474
	CSP	**1.163 [Δ0.009]**	0.545
	Standard ICL	1.095 [Δ0.077]	0.565
	SP-ICL	1.153 [Δ0.019]	0.614
	SC-ICL	1.228 [Δ0.056]	**0.690**
VSM	**Human**	1.167	1.000
	Vanilla	1.014 [Δ0.153]	0.236
	CSP	**1.036 [Δ0.131]**	**0.381**

Figure 3: Human and GPT-5 cultural similarity matrices on WVS: (a) human reference and (b)–(d) GPT-5 under increasingly structure-aware prompts.

5.2 Prompt Ablation Analysis

We now ablate the sphere-contrastive prompt to identify which structural cues carry the signal and on which questions they are most effective (Figure 4).

Experimental details. We vary the sphere-aware ICL prompt on WVS along two axes: the number of retrieved demonstrations (1, 3, and 5 shots) and the included structural cues. For each shot count, **Base** is SP-ICL, and the other variants add combinations of three cues: (i) **same-sphere agreement (SSA)** lists same-sphere cultures whose modal answer matches the target culture's; (ii) **same-sphere disagreement (SSD)** adds those whose modal answer differs; and (iii) **cross-sphere contrast (CS)** adds answers from the most distant sphere. The three-shot Base+SSA+CS configuration is the full SC-ICL prompt used in Section 4.1. See Appendix E.1 for details.

To locate where each cue helps, we split culture–question pairs by same-sphere consensus. For question q in sphere s, the *consensus score* is $\kappa(s,q) = \frac{1}{|\mathcal{C}_s|} \sum_{c \in \mathcal{C}_s} \mathbf{1}\{y_{c,q} = m_{s,q}\}$, the fraction of cultures whose top-1 answer matches the modal response $m_{s,q}$. A pair (c,q) is High-Consensus if $\kappa(s(c),q) = 1$ and Low-Consensus otherwise (Appendix F.1).

Result analysis. As shown in Figure 4, additional demonstrations yield limited gains, which grow from one to three shots and then plateau. This contrast suggests that the improvement comes primarily from the cross-cultural evidence included with each demonstration, rather than from adding demonstrations alone.

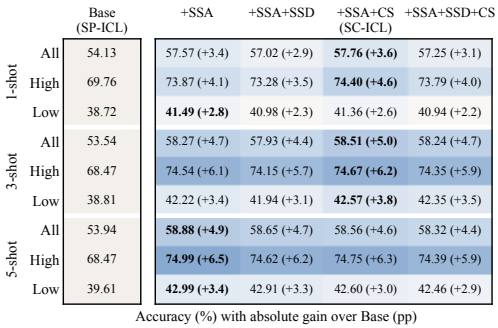

Figure 4: WVS prompt ablation averaged over 10 models. Low and High denote low- and high-consensus questions, respectively. Cells report accuracy (%) and gains over **Base** (pp); darker cells indicate larger gains, and **bold** marks the best result per row.

Among the structural cues, same-sphere agreement (SSA) accounts for the largest gain and concentrates on high-consensus questions where the sphere genuinely shares a common answer. On high-consensus pairs, SSA lifts WVS accuracy by $+4.1$ to $+6.5$ pp over Base across one to five shots, while on low-consensus ones, the advantage is smaller ($+2.8$ to $+3.4$ pp), with the gap widening at higher shot counts. Same-sphere disagreement (SSD) dilutes the benefit of presenting agreement alone. Cross-sphere contrast (CS) has a small and inconsistent marginal effect, with no clear consensus-dependent pattern. Overall, SC-ICL combines the primary SSA signal with CS as a complementary reference for cross-cultural structure.

5.3 Cultural Resource Analysis

Finally, we test whether sphere-aware prompting yields larger gains for low-resource cultures.

Experimental details. We divide cultures into high- and low-resource groups based on their coverage in web corpora representative of LLM pretraining (Joshi et al., 2020; Blasi et al., 2022; Kazemi et al., 2024). Each group contains eight cultures from several spheres (e.g., the United States in the high-resource group and Pakistan in the low-resource group). We compare gains between groups and reuse the WVS High-/Low-Consensus split from Section 5.2 to locate where they concentrate. See Appendix C.2 for group lists and corpus statistics.

Table 4: WVS accuracy (%) by resource group and consensus level, averaged over 10 models. Parentheses show gains over Vanilla (pp). Bold marks the larger group gain.

Consensus	Group	Vanilla	+SSA	SC-ICL
High	Low-res	66.05	74.78 **(+8.7)**	74.99 **(+8.9)**
	High-res	72.11	76.46 (+4.4)	76.92 (+4.8)
Low	Low-res	36.20	41.06 (+4.9)	42.47 **(+6.3)**
	High-res	38.88	44.44 **(+5.6)**	44.46 (+5.6)

(a) Absolute gain by resource group (pp)

(b) Prior-nearest ratio R_{PN}

Figure 5: Resource-group analysis of sphere-aware prompting (SC-ICL on WVS and CSP on VSM). **(a)** Absolute gain over Vanilla (pp) by model; dashed lines show group means. **(b)** Prior-nearest ratio R_{PN} for low-resource cultures, averaged over 10 models; values above 1 indicate that the assigned sphere is closest. MAC and AND lack Hofstede scores. Appendix Table 24 gives individual values.

Result analysis. As shown in Figure 5 and Table 4, *sphere-aware prompting yields larger gains for low-resource cultures, particularly on high-consensus questions*. As shown in Figure 5(a), sphere-

contrastive prompting (SC-ICL) yields $+7.5$ pp on WVS for the low-resource group versus $+5.1$ pp for the high-resource group. VSM shows the same pattern.

As shown in Table 4, this advantage is larger on high-consensus questions, where the low-resource gain nearly doubles the high-resource gain ($+8.9$ vs. $+4.8$ pp). On low-consensus questions, both groups gain comparably. The comparison between +SSA and SC-ICL shows that same-sphere agreement primarily drives this narrowing, consistent with the preceding ablation.

We next test whether sphere-aware prompting shifts cultural profiles toward their assigned spheres. We define the *prior-nearest ratio* $R_{\mathrm{PN}}(c) = \frac{\mathrm{align}(c, s(c))}{\max_{s \neq s(c)} \mathrm{align}(c,s)}$, where $\mathrm{align}(c, s)$ measures how closely c's responses match sphere s. For WVS, this is the fraction of questions on which c matches s's modal answer, and for VSM, it is the normalized similarity between c's dimension scores and the leave-one-out sphere centroid. Values above 1 mean c stays closest to its own sphere (Appendix F.3). Figure 5(b) presents the results. Under culture-only prompting (Vanilla), the low-resource group averages $R_{\mathrm{PN}} = 0.904$, meaning its members sit closer to a foreign sphere than to their own. Sphere-contrastive prompting raises this to 0.979 and increases the ratio for every member. Thus, the sphere prior partially restores these cultures' alignment with their assigned spheres.

6 Can Cultural-Sphere Structure Support Alignment When Target-Culture Data Is Unavailable?

Sections 4 and 5 show that sphere-aware prompting activates encoded cultural knowledge to improve alignment but requires such knowledge to be present in the model. Such knowledge may be incomplete or absent in smaller open-weight models, especially for cultures underrepresented in pretraining data. In these settings, improving cultural alignment may require additional supervision, which is often scarce or unavailable for low-resource and cold-start cultures. We therefore ask whether cultural-sphere structure supports alignment without target-culture supervision.

Section 5 further shows that same-sphere agreement provides the strongest signal for cultural alignment. This suggests using sphere consensus as proxy supervision for cold-start cultures without target-culture labels. We investigate *(1) whether sphere consensus provides effective supervision for held-out cultures* and *(2) whether the gains transfer to an unseen evaluation domain*.

6.1 Experiment Details

Method. We instantiate the cultural-sphere prior through two complementary fine-tuning mechanisms, each with SFT followed by DPO (Algorithm 1). Let $\mathcal{L} \subset \mathcal{C}$ denote the held-out cultures. For each sphere s, we compute three quantities from its non-held-out members $\mathcal{C}_s \setminus \mathcal{L}$: the *sphere consensus* $m_{s,q}$, the modal answer to q; the *consensus score* $\kappa(s, q)$, the fraction of these members agreeing with $m_{s,q}$; and the *most distant sphere* $s^-(s)$, which has the highest mean Jensen–Shannon distance from s.

The *data-augmented* mechanism generates pseudo labels for held-out cultures. **SFT-Aug** assigns $m_{s(c),q}$ as a pseudo-label for each held-out culture $c \in \mathcal{L}$ and jointly fine-tunes with real answers from non-held-out cultures. **DPO-Aug** (Rafailov et al., 2023) then constructs preference pairs, with $m_{s(c),q}$ as the chosen response and an answer from $s^-(s(c))$ as the rejected response, retaining only pairs where $\kappa(s(c), q) > 0.5$. Neither stage uses real labels from held-out cultures.

The *prompt-augmented* mechanism uses no pseudo-labeled data for held-out cultures. **SFT-CSP** and **DPO-CSP** train only on the 33 non-held-out cultures, with cultural-sphere context appended to each instance. This tests whether learning to use sphere information transfers from observed to held-out cultures.

Setting. The held-out design simulates cultures with no data of their own, for which neither gold-answer prompting nor standard fine-tuning is available. We compare our sphere-augmentation method against three reference levels. **SFT-Naive** fine-tunes on the 33 non-held-out cultures without sphere augmentation (lower reference). **Prompting baselines** (Vanilla, CSP, SC-ICL) are applied to the base models, with SC-ICL using same-sphere pseudo-labels because held-out answers are unavailable. Grey **oracle baselines** (SFT-Oracle, DPO-Oracle) fine-tune with held-out labels (upper reference). All fine-tuning uses Qwen3 at 4B, 8B, and 14B scales.

Data. CulturePark (Li et al., 2024b) generates all fine-tuning data from multi-agent debates seeded with the same 50 WVS questions used for ICL demonstrations (Appendix E), disjoint from the 149 evaluation questions. Of 41 cultures, we hold out the eight low-resource cultures from Section 5.3. Using the metrics in Section 3.2, WVS evaluates in-domain transfer on all eight, while VSM evaluates transfer to an unseen domain on the six with Hofstede scores.[4] See Appendix G for details.

Table 5: Results across three Qwen3 scales. Shaded **Low** columns report held-out-culture performance. Parentheses show relative changes (%) from Vanilla, and bold marks the best non-oracle result per column. † Oracle rows use held-out labels as upper references. ‡ SC-ICL uses same-sphere pseudo-labels.

6.2 Results

Table 5 reports held-out performance across three model scales and supports three findings.

(1) *Prompting alone provides limited cold-start improvements.* The cultural-sphere prompt improves held-out accuracy by at most $+2.5\%$ and prompting baselines remain below the next-scale Vanilla baseline. (2) *Sphere-based proxy supervision is an effective training signal.* Gains of SFT-Naive over Vanilla diminish at larger scales without sphere augmentation, whereas gains from SFT-Aug remain consistent through sphere-consensus pseudo-labeling. On Qwen3-14B, SFT-Aug surpasses the oracle (55.12% vs. 52.27%), likely because the consensus serves as a denoised aggregation. DPO-Aug with a distant-sphere contrast further closes the gap, reaching oracle-level WVS accuracy at 4B and 14B. (3) *The resulting alignment extends to an unseen evaluation paradigm at the larger scales*, with DPO-Aug yielding the best VSM similarity at 8B and 14B. The 4B model is an exception, where fine-tuning produces negligible or negative VSM changes for held-out groups and the prompt-augmented variant outperforms the data-augmented one on WVS (44.13% vs. 41.69%), suggesting limited capacity for cross-cultural transfer at this scale. At larger scales, sphere-based augmentation provides effective proxy supervision for cultures with no target-specific data, with gains that generalize beyond the training objective.

7 Conclusion

Existing cultural alignment methods primarily treat cultures as independent alignment targets, leaving relationships among cultures largely underutilized. In contrast, this work studies cultural alignment from a relational perspective, investigating cultural-sphere structure as an explicit prior for both characterizing individual cultures and transferring alignment signals across related societies. Across ten LLMs and three benchmarks, sphere-aware prompting improves alignment and recovers more human-like cultural structure, with larger gains for low-resource cultures. When target-specific labels are unavailable, same-sphere consensus substantially improves alignment and supports transfer to an unseen benchmark. Our analysis uses eight fixed spheres and does not capture within-society variation; future work should explore finer-grained cultural groupings learned from data. Limitations and future work are discussed in Appendix A.

[4] PRISM is excluded because its coverage and open-ended format differ from WVS. Appendix A discusses this cross-format limitation.

AI USE STATEMENT

We wrote this manuscript and used generative AI tools only to revise it, by polishing wording and shortening passages. Generative AI was also used as a coding aid in the experimental section, specifically for writing the plotting and table-generation scripts that render the figures and tables from our result files. It was not used for research ideation, study design, the experimental protocol, or the interpretation of results, and no other disclosure category applies. We designed, ran, and verified all experiments reported here on our own code and data, and checked every figure and table against the underlying result files. The reported numbers are therefore faithful to the experiments we ran, and the analyses and conclusions are our own. We have reviewed all AI-assisted work and take responsibility for the final content of this work, including text, claims, and artifacts produced with the aid of generative AI.

ETHICS STATEMENT

This work models country-level cultures and groups them into eight coarse spheres to improve the cultural alignment of LLMs. We summarize the ethical considerations this design raises below.

- *Risk of cultural essentialism.* Countries and spheres are both aggregates, so they flatten within-country variation, and supervising a held-out culture with its neighbours' consensus (Section 6) can let a regionally dominant voice stand in for a smaller one. We therefore treat the spheres as imperfect coarse structure rather than ground truth, report the prior-nearest ratio in Section 5.3 because a country should not be collapsed into its neighbours, and state the limitation in Section 7. Sphere supervision is a fallback when in-country data are unavailable, not a substitute for collecting them.
- *Scope of the measurements.* The instruments we measure against, the World Values Survey, the Hofstede dimensions, and the Inglehart–Welzel map, are themselves contested summaries of culture, so a higher score means closer agreement with those instruments and not alignment with any individual. Our high-/low-resource split likewise refers only to representation in web corpora.
- *Data and privacy.* We collected no new human-subject data and used only publicly released resources within their licences, namely aggregate country-level statistics for WVS and Hofstede and, for PRISM, records anonymized by its creators, from which we report only country-level aggregates and attempt no re-identification. Our CulturePark training data are model-generated from WVS seed questions and contain no personal information.
- *Responsible use.* Culture-conditioned models are dual use, and we would discourage deployments that assign values to a person based on inferred nationality.

REPRODUCIBILITY STATEMENT

The paper is written so that every reported number can be traced to a stated procedure. Since the page limit leaves room only for brief descriptions in the main text, we provide (1) the alignment objective and the scoring protocol for each benchmark in Appendix B, (2) the country selection, the retained question set, and the corpus statistics behind the high-/low-resource split in Appendix C, (3) the five prompt templates verbatim, together with the BM25 retrieval protocol for the in-context demonstrations, in Appendix E, and (4) the judge prompt and scoring protocol behind the open-ended results in Appendix C.5. We further provide (5) the definitions of the three diagnostics used in the analyses in Appendix F, (6) the two-stage fine-tuning procedure as pseudocode, including which countries enter each statistic, in Appendix G, and (7) the complete per-model and per-sphere tables behind every averaged number in the main text, in Appendix H. We will release the code and data necessary to reproduce our results upon acceptance.

A LIMITATIONS

This work proposes cultural-sphere priors for improving LLM cultural alignment and evaluates them across survey and open-ended benchmarks. We discuss three of its limitations below.

Dependence on a single cultural taxonomy. We instantiate all cultural relations with the eight Inglehart–Welzel spheres, which we adopt because they cover a broad range of cultures and provide explicit cultural groupings. However, no single framework offers a definitive organization of cultures. Other frameworks characterize cultural relations along different dimensions (Hofstede et al., 2010; Schwartz, 1999), from which alternative groupings can be derived. We use the Hofstede dimensions only as the VSM evaluation benchmark and do not test whether our findings persist when the cultural groupings are drawn from these frameworks. We also treat the 2023 World Cultural Map as a fixed snapshot (World Values Survey, 2023), although cultural values and relations can change across cohorts and over time (Inglehart & Baker, 2000). Future work should therefore test the prior across multiple taxonomies and time periods.

Reliance on an LLM judge. We score all open-ended responses with the same GPT-4o judge, rubric, and rated PRISM reference responses, both in the main prompting experiments (Table 1) and in the fine-tuning transfer evaluation (Table 6). This shared setup keeps scores comparable across settings but cannot remove the judge's own cultural biases or its sensitivity to response style and rubric wording. The judge scores are therefore operational measures rather than substitutes for human assessment and should be validated with culturally diverse human raters and independent judges.

Limited transfer across response formats. Our fine-tuning data come exclusively from WVS, where models learn to produce short answers to closed-form survey questions, whereas PRISM requires open-ended responses. We find that the fine-tuning gains reported in Section 6.2 do not carry over to this format. Every fine-tuned checkpoint scores below the untuned Vanilla checkpoint at all three model scales, with relative drops between 9.4% and 15.9% (Table 6).

Despite this decline, the strongest sphere-aware method at each scale (DPO-CSP at 4B and 8B, and DPO-Aug at 14B) still scores above SFT-Naive, although not every sphere-aware variant does. The sphere prior thus retains a modest advantage outside the training format but does not prevent the decline itself.

Table 6: Open-ended PRISM transfer of Qwen3 fine-tuning, measured by the PRISM judge score (1–100) from a GPT-4o judge. Parentheses give the relative change from the untuned Vanilla checkpoint. **Bold** marks the best non-oracle fine-tuned result at each scale; † *Oracle* methods use held-out labels.

Method	Qwen3-4B	Qwen3-8B	Qwen3-14B
Vanilla	69.21	70.16	73.25
CSP	70.34 (+1.6)	71.54 (+2.0)	73.58 (+0.5)
SFT-Naive	59.84 (−13.5)	59.75 (−14.9)	61.60 (−15.9)
SFT-CSP	59.52 (−14.0)	61.04 (−13.0)	63.35 (−13.5)
SFT-Aug	60.08 (−13.2)	60.25 (−14.1)	63.59 (−13.2)
SFT-Oracle†	59.48 (−14.1)	60.27 (−14.1)	63.82 (−12.9)
DPO-CSP	**62.68** (−9.4)	**62.57** (−10.8)	64.62 (−11.8)
DPO-Aug	59.15 (−14.5)	60.80 (−13.3)	**65.60** (−10.4)
DPO-Oracle†	60.79 (−12.2)	60.14 (−14.3)	63.45 (−13.4)

Response length offers secondary evidence of this format shift. Across the three scales, Vanilla responses average 28.0 words and SFT-Naive responses 13.4 words (626 responses per scale). On one 4B item about questioning a friend over a lie without causing conflict, Vanilla gives a tactful formulation that scores 82, while SFT-Naive returns a shorter, generic question that scores 22 and loses the conflict-avoidance framing. This comparison does not establish length as the cause, since relevance, specificity, response style, and the WVS-to-PRISM distribution shift may also contribute. The pattern is nonetheless consistent with the short-answer format of the WVS training data carrying

over into open-ended generation, which calls for open-ended training objectives that preserve the same relational prior.

B Alignment Objectives and Metrics

This appendix expands the unified cultural-alignment objective in Equation 1 and defines the benchmark-specific evaluation protocols used in the paper.

B.1 Prompting and Fine-Tuning Configurations

Equation 1 selects a configuration $\omega \in \Omega$ that minimizes the expected distance D between human and model response distributions. Let $\mathcal{D}_{\text{train}} = \{(q_i, c_i, s_i)\}_{i=1}^{n}$ denote a culturally grounded dataset, where s_i is a supervision signal such as a reference response or a preference pair. Prompting keeps $\theta_\omega = \theta$, so Equation 1 varies only the template,

$$\min_{T_\omega} \mathbb{E}_{c\sim\mathcal{C},\, q\sim Q_c} D(p_c^\star(\cdot \mid q), p_\theta(\cdot \mid T_\omega(q, c))), \tag{2}$$

where T_ω supplies culture-specific information such as a cultural identity, in-context demonstrations drawn from $\mathcal{D}_{\text{train}}$, or explicit norms (Tao et al., 2024; Cao et al., 2023; Choenni & Shutova, 2024; Wang et al., 2025). Fine-tuning instead updates θ_ω. Because $p_c^\star$ is available during training only through the signals in $\mathcal{D}_{\text{train}}$, the expected distance in Equation 1 is replaced by an empirical training loss $\mathcal{L}$,

$$\theta_\omega = \arg\min_\theta \frac{1}{n} \sum_{i=1}^{n} \mathcal{L}(p_\theta(\cdot \mid T_\omega(q_i, c_i)), s_i). \tag{3}$$

This formulation covers culturally grounded signals built through augmentation, simulation, or data optimization (Li et al., 2024a;b; Xu et al., 2025; Yao et al., 2026; Zhao et al., 2026).

B.2 Evaluation Protocols

Survey accuracy. For a survey question q with options $\mathcal{A}(q)$, let $\hat{a}_\theta(q, c)$ be the model's parsed answer and $y_{c,q} = \arg\max_{a\in\mathcal{A}(q)} p_c^\star(a \mid q)$ the dominant human answer. Culture-level accuracy is

$$\text{Acc}_c = \frac{1}{|Q_c|} \sum_{q\in Q_c} \mathbf{1}[\hat{a}_\theta(q, c) = y_{c,q}]. \tag{4}$$

WVS uses this protocol over the retained survey questions. An item left unanswered or returned in unparsable form counts as incorrect, so $|Q_c|$ is always the full set of retained questions (149 for WVS). The reported aggregate is a culture-level macro-average, $\text{Acc} = \frac{1}{|\mathcal{C}|} \sum_{c\in\mathcal{C}} \text{Acc}_c$.

Representation similarity. When a benchmark represents each culture by a vector $r_c^\star$, we compare it with the model representation $r_{\theta,c}$ using a normalized distance $D \in [0, 1]$:

$$\text{Sim}_c = 1 - D(r_c^\star, r_{\theta,c}). \tag{5}$$

For survey response distributions, the model representation can be built from option-normalized likelihoods $q_{\theta,c}(a_k \mid q) \propto \exp \ell_\theta(a_k \mid T(q, c))$. For VSM, $r_c^\star$ is the culture's Hofstede 6-D vector and we use $\text{Sim}_c = 1 - d/(100\sqrt{6})$. The reported aggregate is likewise a culture-level macro-average over all evaluated cultures.

Open-ended evaluation. For a generated response $\hat{y} \sim p_\theta(\cdot \mid T(q, c))$, a judge model J_ϕ assigns a culture-aware score on a fixed scale, conditioned on the question's rated reference responses. We report the culture-level average

$$\text{Score}_c = \frac{1}{|Q_c|} \sum_{q\in Q_c} J_\phi(q, c, \hat{y}). \tag{6}$$

PRISM uses this protocol with scores in $[1, 100]$, and the reported aggregate is a culture-level macro-average; Appendix C.5 gives the judge, the rubric, and the exact inputs. This follows the broader LLM-as-judge paradigm (Zheng et al., 2023) and recent open-ended cultural-alignment work (Yao et al., 2026; Zhao et al., 2026).

C Dataset Details

C.1 Cultural Sphere Definition

Figure 6 shows the Inglehart–Welzel World Cultural Map that defines our cultural-sphere prior. The map is based on World Values Survey data and groups societies into broad value regions (Inglehart & Baker, 2000; Inglehart & Welzel, 2005; World Values Survey, 2023).

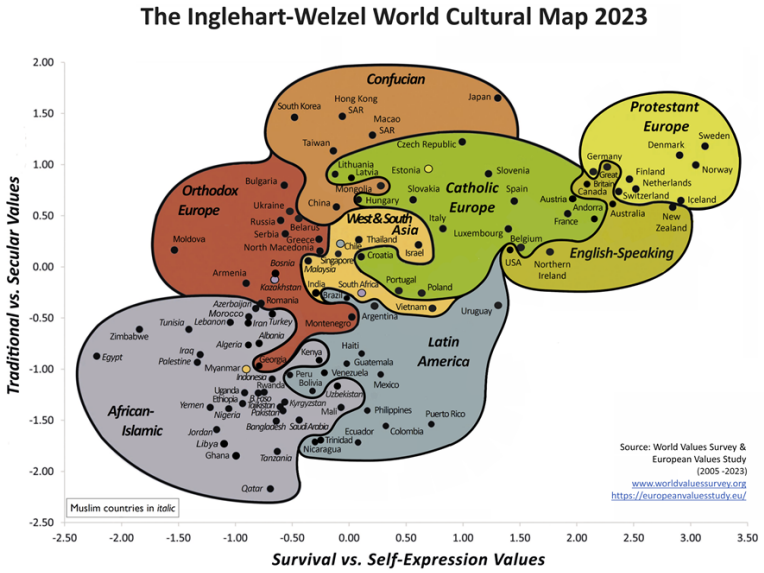

Figure 6: Reprinted from The Inglehart-Welzel World Cultural Map, World Values Survey 7 (2023), source `http://www.worldvaluessurvey.org/` (World Values Survey, 2023).

Table 7 lists all 66 WVS cultures and the sphere each belongs to, in WVS and ISO-style codes, where NIR denotes Northern Ireland. Appendix C.3 gives the 41 cultures retained for evaluation and the reason for that subset.

Table 7: Sphere assignment for all 66 WVS cultures.

Cultural sphere	**Members**
English-Speaking	AUS (Australia), CAN (Canada), GBR (United Kingdom), NIR (Northern Ireland), NZL (New Zealand), USA (United States)
Protestant Europe	DEU (Germany), NLD (Netherlands)
Catholic Europe	AND (Andorra), CZE (Czech Republic), SVK (Slovakia)
Orthodox Europe	ARM (Armenia), GRC (Greece), KAZ (Kazakhstan), ROU (Romania), RUS (Russia), SRB (Serbia), UKR (Ukraine)
Confucian	CHN (China), HKG (Hong Kong), JPN (Japan), KOR (South Korea), MAC (Macao), TWN (Taiwan)
Latin America	ARG (Argentina), BOL (Bolivia), BRA (Brazil), CHL (Chile), COL (Colombia), ECU (Ecuador), GTM (Guatemala), MEX (Mexico), NIC (Nicaragua), PER (Peru), PRI (Puerto Rico), URY (Uruguay), VEN (Venezuela)
African-Islamic	BGD (Bangladesh), EGY (Egypt), ETH (Ethiopia), IDN (Indonesia), IRN (Iran), IRQ (Iraq), JOR (Jordan), KEN (Kenya), KGZ (Kyrgyzstan), LBN (Lebanon), LBY (Libya), MAR (Morocco), MMR (Myanmar), NGA (Nigeria), PAK (Pakistan), TJK (Tajikistan), TUN (Tunisia), UZB (Uzbekistan), ZWE (Zimbabwe)
West & South Asia	CYP (Cyprus), IND (India), MDV (Maldives), MNG (Mongolia), MYS (Malaysia), PHL (Philippines), SGP (Singapore), THA (Thailand), TUR (Turkiye), VNM (Viet Nam)

C.2 High- and Low-Resource Groups

Section 5.3 splits the evaluated cultures into high- and low-resource groups by how strongly each culture appears in the web corpora that dominate LLM pretraining (Joshi et al., 2020; Blasi et al., 2022; Kazemi et al., 2024). Since no published list ranks cultures in this way, we make the criterion concrete with corpus-level statistics computed over CulturaX, a large multilingual web corpus of the kind used for pretraining (Nguyen et al., 2024), and use them to validate the grouping.

Resource proxies. For each culture, we match the URL of every web document in CulturaX against the corresponding country-code top-level domain (ccTLD, for example `.ru` for Russia and `.pk` for Pakistan), and report two statistics. *Matched URL documents* counts the documents whose URL falls under the culture's ccTLD and measures raw document volume, while *unique hosts* counts the distinct web hosts contributing those documents and measures how broadly the content is sourced. We treat unique hosts as the more reliable indicator, because document volume can be inflated by a small number of prolific hosts.

Table 8: CulturaX ccTLD resource statistics for the high- and low-resource groups.

High-resource group			Low-resource group		
Culture	**Matched URL documents**	**Unique hosts**	**Culture**	**Matched URL documents**	**Unique hosts**
Netherlands (NLD)	767,234	213,366	Pakistan (PAK)	181,630	1,588
Russia (RUS)	759,314	252,806	Philippines (PHL)	34,060	1,600
Germany (DEU)	615,890	214,145	Morocco (MAR)	14,353	1,883
Japan (JPN)	277,014	82,503	Peru (PER)	12,125	2,663
China (CHN)	187,460	110,749	Egypt (EGY)	8,788	759
United Kingdom (GBR)	74,428	32,581	Nigeria (NGA)	1,836	932
Canada (CAN)	44,505	17,451	Macao SAR (MAC)	626	125
United States (USA)	23,035	8,029	Andorra (AND)	53	32

Validation. Table 8 supports the grouping in two ways. First, unique hosts separate the two groups cleanly, since the lowest high-resource value (USA, 8,029) still exceeds the highest low-resource value (PER, 2,663). Second, raw document counts agree on average but are not strictly separated, because Pakistan and the Philippines reach larger document volumes than the United States while drawing on far fewer hosts, so their volume is concentrated on a small number of sites.

ccTLD matching has a known bias. Much of the content from English-speaking cultures lives on generic domains such as `.com`, `.org`, and `.net` rather than `.us`, `.ca`, or `.uk`, so ccTLD-only counts understate their true coverage. Even under this conservative undercount, the unique hosts of the English-speaking members of the high-resource group remain well above the entire low-resource group, so the grouping is robust to this bias.

An independent proxy points the same way. Dodge et al. (2021) geolocate the hosts of the English subset of C4 and report that Pakistan, Nigeria, and the Philippines contribute 0.06%, 0.03%, and 0.1% of the United States URL count. All three are in our low-resource group, so the split rests on corpus evidence rather than on intuition.

C.3 World Values Survey (WVS)

Data and coverage. To support WVS evaluation and WVS-based structural analyses on a common sample, we require a culture pool that covers all eight predefined spheres while retaining broad question coverage and limiting sphere-size imbalance. We use the World Values Survey Round Seven Country-Pooled Datafile, Version 5.0 (Haerpfer et al., 2022), treating each country or region as a culture. From the 66 cultures in the pooled file, we retain a common pool of 41: English-Speaking (USA, GBR, CAN, AUS, NZL, NIR), Protestant Europe (DEU, NLD), Catholic Europe (CZE, SVK, AND), Orthodox Europe (RUS, UKR, ROU, GRC, SRB, ARM), Confucian (CHN, JPN, KOR, TWN, HKG, MAC), Latin America (BRA, MEX, ARG, COL, CHL, PER), African-Islamic (IDN, PAK, NGA, EGY, IRN, MAR), and West & South Asia (IND, TUR, THA, VNM, PHL, MYS).

This selection yields 191 questions with responses shared across all 41 cultures, of which 149 form the predefined evaluation set listed below. Retaining all 66 cultures would reduce the common coverage to 177 questions and the evaluation set to 140, while producing a more imbalanced sphere distribution: African-Islamic and Latin America would contain 19 and 13 cultures, respectively, whereas Protestant Europe and Catholic Europe would contain only two and three. The 41-culture subset therefore provides broader shared question coverage and a less imbalanced basis for cross-sphere comparisons.

Human reference. To score model responses and construct a common representation for WVS-based structural analyses, we reduce each culture–question response profile to a single Top-1 human label. For each retained culture c and question q, let $p_c^\star(a \mid q)$ denote the observed culture-level response proportion for option $a \in \mathcal{A}(q)$. We define the label as the modal option,

$$y_{c,q} = \arg \max_{a \in \mathcal{A}(q)} p_c^\star(a \mid q), \tag{7}$$

where ties are resolved by the smallest numeric answer label when available and otherwise by lexicographic order. We require a valid label for every culture on each retained question. This procedure produces the full 41×149 human-reference matrix used for WVS accuracy and WVS-based structural analyses. For method-specific structural comparisons, the human and model matrices are restricted to the same commonly parsable question subset (Appendix H.3). We keep the 149 evaluation questions disjoint from the 50 WVS questions used to construct the ICL demonstration pool and the CulturePark fine-tuning data (Appendix E), preventing evaluation questions from entering either source of model supervision.

Table 9 illustrates the construction using WVS Q6 on the importance of religion. Applying the same modal rule yields all four response labels across the eight cultural spheres, preserving cross-cultural variation for a question shared by every culture. The table reports only the four substantive response options, so the displayed proportions may sum to less than one.

Table 9: Construction of Top-1 human answers for WVS Q6 ("How important is religion in your life?"). Values are culture-level response proportions for the four substantive options; bold marks the modal response selected as Top-1.

Culture	Cultural sphere	Response proportion				Top-1 answer
		Very	Rather	Not very	Not at all	
Egypt	African-Islamic	**0.973**	0.027	0.000	0.000	Very important
India	West & South Asia	**0.634**	0.212	0.096	0.050	Very important
Brazil	Latin America	**0.455**	0.396	0.101	0.045	Very important
United States	English-Speaking	**0.331**	0.237	0.227	0.199	Very important
Russia	Orthodox Europe	0.180	**0.325**	0.310	0.158	Rather important
Germany	Protestant Europe	0.139	0.246	**0.352**	0.259	Not very important
China	Confucian	0.038	0.099	**0.433**	0.421	Not very important
Czech Republic	Catholic Europe	0.067	0.159	0.278	**0.494**	Not at all important

Retained questions. To make the evaluation set exactly reproducible, we report the 149 retained questions in the following QID ranges:

Q1–Q21; Q23–Q24; Q26; Q42–Q64; Q66–Q68; Q72–Q75; Q77–Q81; Q94–Q112; Q120–Q121; Q131; Q142–Q143; Q149–Q150; Q152–Q157; Q163–Q164; Q166–Q168; Q171–Q173; Q176–Q181; Q184–Q185; Q187–Q188; Q190–Q191; Q195; Q199–Q206; Q208–Q214; Q216; Q221; Q235–Q236; Q238–Q239; Q241–Q244; Q246–Q251; Q253–Q255; Q257–Q259.

C.4 Hofstede 6-D Scores

Data and coverage. VSM evaluates alignment against continuous cultural profiles. We use the Hofstede 6-D scores published by The Culture Factor as the human reference (Hofstede et al., 2010; Hofstede & Minkov, 2013; The Culture Factor Group, 2026) and derive model profiles from the 24 VSM 2013 items. Both use six dimensions: Power Distance Index (PDI), Individualism (IDV), Masculinity (MAS), Uncertainty Avoidance Index (UAI), Long-Term Orientation (LTO), and Indulgence (IVR).

We retain 37 of the 41 WVS cultures to keep coverage fixed across models and prompting methods. AND and MAC lack published six-dimensional scores, while NIR and VNM lack a complete set of model responses. GBR is matched to the published United Kingdom profile. The retained pool spans all eight spheres; the fine-tuning transfer analysis uses its six eligible held-out cultures (Section 6.1). Table 10 gives the full coverage.

Table 10: The 37 cultures retained for prompting-based VSM evaluation and Hofstede 6-D structural analyses.

Sphere	Cultures	n
English-Speaking	USA, GBR, CAN, AUS, NZL	5
Protestant Europe	DEU, NLD	2
Catholic Europe	CZE, SVK	2
Orthodox Europe	RUS, UKR, ROU, GRC, SRB, ARM	6
Confucian	CHN, JPN, KOR, TWN, HKG	5
Latin America	BRA, MEX, ARG, COL, CHL, PER	6
African-Islamic	IDN, PAK, NGA, EGY, IRN, MAR	6
West & South Asia	IND, TUR, THA, PHL, MYS	5
Total		**37**

Representation and similarity. Each culture c is represented by

$$\mathbf{v}_c = [\mathrm{PDI}_c, \mathrm{IDV}_c, \mathrm{MAS}_c, \mathrm{UAI}_c, \mathrm{LTO}_c, \mathrm{IVR}_c]. \tag{8}$$

The human vector contains the published scores. The model vector is computed from its 24 Likert responses using the VSM formulas (Hofstede & Minkov, 2013); for example, $\mathrm{PDI} = 35(m_7 - m_2) + 25(m_{20} - m_{23})$. Each raw dimension is rescaled to $[0, 100]$ using its theoretical extrema.

For two profiles $\mathbf{u}, \mathbf{v} \in [0, 100]^6$, we define

$$s_{6\mathrm{D}}(\mathbf{u}, \mathbf{v}) = 1 - \frac{\|\mathbf{u} - \mathbf{v}\|_2}{100\sqrt{6}}. \tag{9}$$

The score lies in $[0, 1]$ and equals 1 for identical profiles. Model–human similarity for the same culture gives the VSM alignment metric; pairwise human or model similarities form the matrices used in the structural analyses.

C.5 PRISM

Data and coverage. PRISM supports open-ended cultural evaluation through values-guided interactions and rated model responses (Kirk et al., 2024). We use a subset of 626 prompts spanning 13 cultures and six cultural spheres, where 12 cultures contribute 50 prompts each and Korea contributes 26. Table 11 gives the per-sphere breakdown.

Table 11: Coverage of the PRISM values-guided evaluation subset. Parentheses give the ISO code and number of prompts for each culture.

Cultural sphere	Members (ISO, prompts)	Total
English-Speaking	Australia (AUS, 50), Canada (CAN, 50), New Zealand (NZL, 50), United Kingdom (GBR, 50), United States (USA, 50)	250
Latin America	Chile (CHL, 50), Mexico (MEX, 50)	100
Protestant Europe	Germany (DEU, 50), Netherlands (NLD, 50)	100
Confucian	Japan (JPN, 50), Korea, Republic of (KOR, 26)	76
Catholic Europe	Czechia (CZE, 50)	50
Orthodox Europe	Greece (GRC, 50)	50

Evaluation items and references. Each item contains an interaction ID, the culture and its ISO code, the system prompt used to generate the candidate, a user prompt, and one to four rated PRISM reference responses. The fixed reference set comprises 2,044 responses from 21 models. Each evaluated model generates a new candidate for the same user prompt, while the references remain unchanged across models and methods, placing all candidates on a common rated scale.

Model-judge evaluation. Open-ended prompts have no single gold answer, so GPT-4o scores each candidate against the rated responses to the same prompt. For item i, the judge J_ϕ receives the culture c_i, the cultural system prompt p_i^{sys}, the user prompt x_i, the candidate response $\hat{y}_i$, and the reference set $\mathcal{R}_i$ with its released PRISM ratings, and returns

$$\text{score}_i = J_\phi(c_i, p_i^{\text{sys}}, x_i, \hat{y}_i, \mathcal{R}_i) \in \{1, 2, \ldots, 100\}. \tag{10}$$

The references calibrate the scale rather than serve as targets, since the judge uses their ratings to assess response quality without rewarding surface similarity. We average scores within each culture and then macro-average across the 13 cultures,

$$\text{Score}_{\text{PRISM}} = \frac{1}{|\mathcal{C}|} \sum_{c \in \mathcal{C}} \frac{1}{|Q_c|} \sum_{i \in Q_c} \text{score}_i, \tag{11}$$

so each culture contributes equally despite the unequal item counts in Table 11.

We call GPT-4o once per item using the fixed rubric below, constrain its output to JSON, and round and clip the score to $[1, 100]$. Holding the judge, rubric, and references fixed makes scores comparable across models and methods. Because GPT-4o is also an evaluated model, its PRISM results may reflect self-preference.

Judge prompt template. The evaluation uses the prompts below, with each reference rendered as its model name, released PRISM score, and response text.

System prompt
You are a strict but fair LLM judge. Your task is to score how well the candidate response matches the cultural values and perspective of the specified country background. Use all reference responses as evidence for the expected cultural framing, tone, values, and stance. Give more weight to higher-scored reference responses, but consider the whole set. Focus primarily on cultural value alignment with the specified country background. Secondarily consider relevance, clarity, helpfulness, and whether the reply stays brief when asked. A high score means the candidate sounds culturally plausible for that country and is consistent with the reference set's value orientation. Return valid JSON only with this exact schema:

```
{"score": 1, "reason": "short explanation"}
```

User prompt
Evaluate the candidate response for cultural value alignment.
Country: `[COUNTRY]`
System prompt: `[CULTURAL_SYSTEM_PROMPT]`
User prompt: `[USER_PROMPT]`
Candidate response: `[CANDIDATE_RESPONSE]`
Reference responses: `[REFERENCE_BLOCK]`, where each entry gives `Model`, `Reference score`, and `Reference response`
Instructions:

- Infer the country's likely cultural values and response style from the full reference set.
- Score the candidate on how well it matches that cultural perspective.
- Do not average the reference scores mechanically.
- Use the reference scores as quality hints, not as labels to copy.

Scoring guidance:

- 1 to 20: strongly misaligned with the country's cultural values or clearly off-prompt.
- 21 to 40: weak cultural alignment.
- 41 to 60: partial or mixed alignment.
- 61 to 80: good cultural alignment.
- 81 to 100: very strong cultural alignment and a natural fit for the country's perspective.

Return JSON only.

D VALIDATING THE CULTURAL-SPHERE PRIOR

We use the eight Inglehart–Welzel cultural spheres as a prior over cultures, with the full assignment in Appendix C.1. Developed from World Values Survey research, the framework groups societies along two aggregate dimensions: traditional versus secular-rational values and survival versus self-expression values (Inglehart & Baker, 2000; World Values Survey, 2023). The framework is widely used in cross-cultural social science and has also been applied to analyses of cultural bias in LLMs (Tao et al., 2024).

Since our method relies on these spheres, we verify that they reflect structure in empirical cultural data. We first test whether cultures are more similar within the same sphere than across spheres, including whether this pattern is stable across value topics, and then compare the predefined spheres with data-driven clusters.

D.1 WITHIN-SPHERE SIMILARITY EXCEEDS BETWEEN-SPHERE SIMILARITY

Within–between comparison. To test whether the spheres correspond to measurable similarity in human data, we compare within-sphere and between-sphere similarity on two complementary human references, the 41×149 WVS Top-1 matrix and the published Hofstede 6-D profiles for 37 cultures. Appendix C.3 and Appendix C.4 give their construction and coverage. The prior predicts that cultures in the same sphere are more similar than cultures in different spheres.

For WVS, similarity is the fraction of retained questions on which two cultures share the same Top-1 human answer:

$$s_{\mathrm{WVS}}(c_i, c_j) = \frac{1}{|Q|} \sum_{q \in Q} \mathbf{1}\left[y_{c_i,q} = y_{c_j,q}\right]. \tag{12}$$

For Hofstede 6-D, we use the normalized profile similarity from Appendix C.4:

$$s_{\mathrm{6D}}(c_i, c_j) = 1 - \frac{\|\mathbf{v}_{c_i} - \mathbf{v}_{c_j}\|_2}{100\sqrt{6}}. \tag{13}$$

For sphere g with members $\mathcal{C}_g$, we compute

$$\mathrm{Within}(g) = \frac{2}{|\mathcal{C}_g|(|\mathcal{C}_g| - 1)} \sum_{\substack{c_i, c_j \in \mathcal{C}_g \\ i<j}} s(c_i, c_j), \tag{14}$$

$$\mathrm{Between}(g) = \frac{1}{|\mathcal{C}_g|\,|\mathcal{C} \setminus \mathcal{C}_g|} \sum_{c_i \in \mathcal{C}_g} \sum_{c_j \notin \mathcal{C}_g} s(c_i, c_j). \tag{15}$$

Their ratio tests this prediction directly, since a value above 1 indicates greater within-sphere similarity. The Average row in Table 12 is an unweighted macro-average over spheres.

Table 12: Pairwise human similarity within and outside each predefined cultural sphere. Ratio is within-sphere similarity divided by between-sphere similarity; Average is an unweighted macro-average over spheres.

Cultural sphere	WVS			Hofstede 6-D		
	Within	Between	Ratio	Within	Between	Ratio
English-Speaking	0.799	0.611	1.308	0.924	0.674	1.370
Protestant Europe	0.805	0.626	1.286	0.736	0.657	1.121
Catholic Europe	0.752	0.650	1.157	0.729	0.704	1.035
Orthodox Europe	0.734	0.651	1.127	0.852	0.705	1.209
Confucian	0.698	0.610	1.145	0.764	0.671	1.139
Latin America	0.691	0.627	1.102	0.828	0.696	1.190
African-Islamic	0.706	0.612	1.153	0.801	0.689	1.163
West & South Asia	0.697	0.636	1.096	0.806	0.728	1.108
Average	**0.735**	**0.628**	**1.172**	**0.805**	**0.690**	**1.167**

As shown in Table 12, all eight spheres have ratios above 1 in both datasets. The macro-average ratio is 1.172 for WVS and 1.167 for Hofstede 6-D. English-Speaking shows the strongest separation in both datasets, whereas West & South Asia in WVS (1.096) and Catholic Europe in Hofstede 6-D (1.035) have ratios closest to 1. Replication across the two human references shows that the sphere assignments capture a consistent, though uneven, similarity structure.

Topic-level robustness. We next test whether this result is driven by a narrow subset of WVS questions. We analyze the six value topics containing more than ten retained questions and recompute similarity using each topic's question set Q_τ:

$$s_\tau(c_i, c_j) = \frac{1}{|Q_\tau|} \sum_{q \in Q_\tau} \mathbf{1}\left[y_{c_i,q} = y_{c_j,q}\right]. \tag{16}$$

Each topic yields an eight-dimensional within-sphere vector and a 28-dimensional between-sphere vector. We compare each with its 149-question counterpart using Spearman correlation and a one-sided permutation test with 5,000 permutations. To separate topic effects from reduced question coverage, we also draw 3,000 random subsets of the same size from the 149 questions, without replacement, and compute a 95% interval for each sphere or sphere pair. CI share is the proportion of topic-specific values inside these intervals.

Table 13: Topic-level robustness of WVS similarity structure. ρ compares each topic-specific vector with the 149-question vector; p is a one-sided permutation p-value (5,000 permutations; unadjusted for multiple comparisons). CI share is the fraction of values inside the 95% intervals from 3,000 same-size random subsets.

Topic	**#Q**	**Within-sphere**			**Between-sphere**		
		$\boldsymbol{\rho}$	p	**CI share**	$\boldsymbol{\rho}$	p	**CI share**
Social Values	28	0.476	0.117	0.750	0.733	< 0.001	0.607
Happiness	11	0.810	0.009	0.875	0.287	0.067	0.893
Social Capital	32	0.515	0.101	0.500	0.512	0.004	0.536
Ethical Values	13	-0.452	0.877	0.750	0.796	< 0.001	0.786
Political Interest	17	0.452	0.134	1.000	0.728	< 0.001	0.821
Political Regimes	20	0.952	0.001	0.750	0.603	0.001	0.607

Table 13 and Figure 7 show that within-sphere rankings depend on topic. Political Regimes and Happiness closely preserve the all-question ranking ($\rho = 0.952$ and 0.810), whereas Ethical Values reverses much of it ($\rho = -0.452$). Between-sphere structure is more stable, with all six correlations positive and five of them at $p < 0.01$ (Figure 8). For every topic, at least half of the within- and between-sphere values fall inside the same-size random-subset intervals, so reduced question coverage explains part, but not all, of the variation. The sphere prior therefore captures a stable coarse structure rather than a topic-invariant partition.

(e) Political Interest (f) Political Regimes

Figure 8: Topic-level between-sphere similarities in WVS. Each panel compares the all-question between-sphere similarity vector with the vector computed from one value topic.

Table 14: Agreement between data-driven clusters and predefined cultural-sphere labels. Random 97.5% is the 97.5th percentile of the ARI after permuting sphere labels while preserving sphere sizes.

Data	Clustering setting	k	ARI	Random 97.5%	p_{perm}
WVS	Data-driven $k^\star$	3	0.146	0.037	0.0001
WVS	Fixed $k = 8$	8	0.245	0.077	0.0001
Hofstede 6-D	Data-driven $k^\star$	2	0.189	0.054	0.0001
Hofstede 6-D	Fixed $k = 8$	8	0.420	0.081	0.0001

D.2 Agreement with Empirical Value Clusters

To test whether the sphere structure also emerges from the data without supervision, we cluster the WVS and Hofstede 6-D representations used above without sphere labels and compare the resulting partitions with the predefined spheres. The prior implies that this agreement should exceed chance.

Clustering. We use average-linkage agglomerative hierarchical clustering, also known as UPGMA (Sokal & Michener, 1958). For clusters A and B, average linkage defines their distance as

$$D(A, B) = \frac{1}{|A||B|} \sum_{c_i \in A} \sum_{c_j \in B} d(c_i, c_j). \tag{17}$$

For WVS, each culture is represented by its Top-1 answer vector over the 149 retained questions, and $d(c_i, c_j)$ is the normalized Hamming distance. For Hofstede 6-D scores, $d(c_i, c_j) = 1 - s_{6\mathrm{D}}(c_i, c_j)$, using the normalized Euclidean similarity in Appendix C.4.[5]

We evaluate two settings, which answer different questions. The *data-driven optimal* setting selects k from standard internal cluster-validity indices, which use no sphere labels, and shows what granularity the data alone favour. The *fixed culture-sphere* setting sets $k = 8$ to match the number of predefined spheres, which makes the two partitions directly comparable.

Agreement metrics. We measure agreement using the Adjusted Rand Index (ARI), which compares two partitions while correcting for chance agreement (Hubert & Arabie, 1985), so a value near zero indicates chance-level agreement and larger values indicate stronger correspondence. We also run a permutation test that preserves the number of cultures in each cultural sphere. Across 10,000 trials, we randomly permute sphere labels, recompute ARI, and take the 97.5th percentile of the resulting null distribution as the "Random 97.5%" column. The permutation p-value is computed with add-one correction,

$$p = \frac{1 + \sum_{b=1}^{B} \mathbf{1}\left[\mathrm{ARI}^{(b)} \geq \mathrm{ARI}^{\mathrm{obs}}\right]}{B + 1}, \quad B = 10000, \tag{18}$$

so the smallest reportable value is approximately 0.0001.

Results. Table 14 shows that data-driven clusters agree with the cultural-sphere labels in every setting. In WVS the data-driven optimum is three coarse clusters with an ARI of 0.146, and fixing $k = 8$ raises it to 0.245. Hofstede 6-D scores show a similar pattern. The optimal setting selects only $k = 2$, placing a mostly Western and Confucian group in one cluster and Orthodox Europe, Latin America, African-Islamic, and most of West & South Asia in the other. Fixing $k = 8$ raises ARI from 0.189 to 0.420. In both datasets the observed ARI is well above the 97.5th percentile of the permutation null distribution, and the permutation test reaches the minimum reportable value under 10,000 trials ($p_{\mathrm{perm}} = 0.0001$), so the agreement is unlikely to arise merely from the number or size of the predefined spheres.

Figures 9–11 show where the agreement comes from and where it breaks down. In the cluster-to-sphere correspondence of Figure 9, the optimal settings merge several related spheres, while the fixed $k = 8$ setting aligns more finely with individual ones. In that fixed setting, the WVS

[5] We implement clustering with SciPy's `linkage(method="average")` and `fcluster` (Virtanen et al., 2020), and cluster-validity and agreement metrics are computed with scikit-learn (Pedregosa et al., 2011).

(c) WVS, fixed $k = 8$

(d) Hofstede 6-D, fixed $k = 8$

Figure 9: Correspondence between data-driven clusters and predefined cultural spheres. Each panel shows how cultures assigned to an unsupervised cluster are distributed across human-defined cultural-sphere labels.

similarity map in Figure 10 shows English-Speaking members as a compact block with Protestant and Catholic European members attached. Hong Kong, Macao, and South Korea form a separate Confucian cluster, while the remaining Confucian members group with West & South Asian and African-Islamic ones. Latin American, African-Islamic, and West & South Asian members are more interleaved with neighbouring spheres, which keeps the ARI far from 1.

Within-sphere variation and cross-sphere overlap remain, so the spheres are not exact ground-truth labels. Their agreement with data-driven clusters nonetheless stays above chance, which supports using them as a coarse structural prior.

E PROMPTING METHODS

This appendix specifies the generation prompts used in Sections 4, 5, and 6. WVS uses all five prompting variants, whereas VSM and PRISM use only the two zero-shot variants, Vanilla and CSP. The placeholders `[COUNTRY]`, `[COUNTRY_ADJ]`, `[SPHERE]`, and `[PEER_COUNTRIES]` are filled using the target culture and its cultural-sphere assignment in Appendix C.1.

E.1 WVS PROMPTS

Each WVS prompt has a system prompt that defines the target cultural persona and, for ICL settings, a sequence of in-context question–answer examples. The demonstration block is repeated k times before the final test question. All WVS question prompts use the following base format.

Base WVS question template
Given a #Question and #Options, choose the option that best aligns with your own value system to answer the question.
#Question: `[QUESTION]`
#Options: `[OPTION_1]` `[OPTION_2]` ...
Please return the number of the selected option only.

Demonstration retrieval. All ICL variants share one retrieval protocol, so they differ only in what each demonstration carries. Demonstrations are drawn from a fixed pool of 50 WVS questions that is disjoint from the 149 evaluation questions of Appendix C.3, so a test question is never shown as its own demonstration and its gold answer never enters the prompt. For each test question we score every pool question with BM25 ($k_1 = 1.5$, $b = 0.75$, and $\mathrm{idf}(t) = \log\big(1 + (N - \mathrm{df}(t) + 0.5)/(\mathrm{df}(t)+0.5)\big)$) over lowercased alphanumeric tokens, with the question text weighted twice and the answer options once, and rank the pool by score with ties broken by question ID, so the ranking is deterministic and identical across models and methods. We then walk down this ranking and keep the first k questions for which the required evidence exists, that is, at least one same-sphere reference answer and, for SC-ICL, at least one contrastive answer from the most distant sphere. We use $k = 3$ shots unless stated otherwise, and Section 5.2 varies $k \in \{1, 3, 5\}$. For a retrieved demonstration question q_d, `[DEMO_ANSWER]` is the target culture's human Top-1 answer y_{c,q_d} from this separate demonstration pool. It is inserted as the assistant turn paired with `[DEMO_QUESTION]`; it is distinct from the reference-culture `[ANSWER]` values shown inside the structured evidence blocks and from the model's answer to the final test question.

Vanilla. This baseline only specifies the target cultural identity.

System: You are a real person with a `[COUNTRY_ADJ]` cultural background. Please fill out the World Values Survey and answer the questions honestly according to your own value system.
User: Base WVS question template with the test question.

Cultural Sphere Prompt. This setting adds the cultural-sphere prior to the system prompt, but does not use demonstrations.

System: You are a real person with a `[COUNTRY_ADJ]` cultural background. Your country belongs to the `[SPHERE]` culture sphere, which also includes `[PEER_COUNTRIES]`. Use this cultural context to understand your own cultural position and answer the World Values Survey honestly according to your own value system.
User: Base WVS question template with the test question.

Standard ICL. This setting keeps the culture-only system prompt and adds ordinary WVS question-answer demonstrations. The examples do not include cultural-sphere labels or cross-culture evidence.

System: Vanilla system prompt.
Demonstration, repeated k times:
User: Base WVS question template with `[DEMO_QUESTION]`.
Assistant: `[DEMO_ANSWER]`
Final user: Base WVS question template with `[TEST_QUESTION]`.

Sphere-Prompted ICL (SP-ICL). This setting combines the cultural-sphere system prompt with ordinary ICL demonstrations. It tests whether the sphere-level persona helps beyond demonstrations alone.

System: Cultural Sphere Prompt system prompt.
Demonstration, repeated k times:
User: Base WVS question template with `[DEMO_QUESTION]`.
Assistant: `[DEMO_ANSWER]`
Final user: Base WVS question template with `[TEST_QUESTION]`.

Sphere-Contrastive ICL (SC-ICL). Our method keeps the cultural-sphere system prompt and makes each demonstration structurally informative. Each example includes same-sphere member answers and contrastive answers from a distant sphere. The contrastive evidence is used only to clarify cultural differences, while the final answer is still requested from the target culture's perspective. Here `[SAME_SPHERE_REFERENCES]` renders one to three same-sphere member answers, while `[CONTRASTIVE_REFERENCES]` renders one or two distant-sphere member answers.

System: Cultural Sphere Prompt system prompt.
Structured demonstration, repeated k times:
User: Base WVS question template with `[DEMO_QUESTION]`.
Same-sphere agreement (SSA). Within your culture sphere (`[SPHERE]`), these countries most often answer the same way as `[COUNTRY]`: `[SAME_SPHERE_REFERENCES]`
Cross-sphere contrast (CS). The most distant culture sphere from `[SPHERE]` is `[DISTANT_SPHERE]`. For contrast, countries from that sphere answer: `[CONTRASTIVE_REFERENCES]`
Use the contrasting examples only to understand what is different across culture spheres. Now answer this question from the perspective of `[COUNTRY]`. Reply with only the option number.
Assistant: `[DEMO_ANSWER]`
Final user: Base WVS question template with `[TEST_QUESTION]`.

Ablation variants. Section 5.2 switches the two evidence blocks above on and off, at $k \in \{1, 3, 5\}$ shots. **Base** removes both and is therefore SP-ICL. **+SSA** keeps the SSA block alone. **+SSA+SSD** extends the SSA list with same-sphere members whose modal answer differs, with every entry marked as matching or differing ("these countries show both agreement with and variation from `[COUNTRY]`'s most common answer"). **+SSA+CS** is exactly the template above, which is the SC-ICL prompt reported in Section 4.2. **+SSA+SSD+CS** pairs the mixed list with the contrast block.

E.2 VSM AND PRISM ZERO-SHOT PROMPTS

VSM and PRISM reuse the cultural-identity and sphere-context clauses of the WVS prompts, but replace the survey-specific instruction and user message format. To state the differences without repeating the shared text, define the two clauses below.

`[IDENTITY]`: You are a real person with a `[COUNTRY_ADJ]` cultural background.
`[SPHERE_CONTEXT]`: Your country belongs to the `[SPHERE]` culture sphere, which also includes `[PEER_COUNTRIES]`.

VSM. The Vanilla system prompt is `[IDENTITY]`. CSP uses the following system prompt.

System: `[IDENTITY]` Your country is `[COUNTRY]`. `[SPHERE_CONTEXT]` Use this cultural context to understand your own cultural position and fill out the Values Survey Module (VSM13) honestly according to your own value system. Return only one number from 1 to 5 for each question.

Under both methods, the user message preserves the original VSM item and its response scale, drawing on the 24 VSM 2013 items of Appendix C.4.

> **User:** Answer the questions below by choosing an answer from the following: `[RESPONSE_SCALE]` `[VSM_ITEM]` Just give me a NUMBER as your answer.

PRISM. The Vanilla system prompt is again `[IDENTITY]`. CSP uses the following system prompt.

> **System:** `[IDENTITY]` `[SPHERE_CONTEXT]` Use this cultural context to understand your own cultural position and answer naturally according to your own value system.

For both methods, the user message is the original open-ended PRISM prompt, inserted verbatim as `[USER_PROMPT]`. These are the candidate-generation prompts. The system prompt behind a response is the p_i^{sys} that the judge receives, and the judge prompt itself is reported in Appendix C.5.

E.3 Held-Out SC-ICL in Section 6

Vanilla and CSP need no change in the held-out setting, since neither carries any answer of the target culture. SC-ICL does. The standard WVS setting uses y_{c,q_d} as `[DEMO_ANSWER]`, and in the held-out setting, where this target-culture answer is unavailable, we replace it with `[PSEUDO_DEMO_ANSWER]` $= m_{s(c),q_d}$, computed only from non-held-out members of the target sphere. The same-sphere and contrastive reference lists likewise exclude held-out answers. Retrieval, prompt wording, and the final test question remain unchanged.

F Structural Diagnostics

This appendix provides full definitions for the diagnostics used in Section 5: the High-/Low-Consensus split, the within-/between-sphere ratio and human–model structural similarity ρ_{HM}, and the prior-nearest ratio R_{PN}.

F.1 High-/Low-Consensus Split for Ablation Analysis

To test whether structural cues help most when members of a sphere share the same response, we construct the High-/Low-Consensus split from the human WVS reference data before evaluating any model predictions. The split distinguishes sphere–question pairs with unanimous culture-level top-1 answers from those with cross-cultural disagreement.

For each selected WVS question $q \in \mathcal{Q}$ and each cultural sphere $s \in \mathcal{S}$, let $\mathcal{C}_s$ be the set of members in sphere s. We first convert the human response distribution of each culture into a culture-level top-1 answer,

$$y_{c,q} = \arg\max_a p_{c,q}(a), \tag{19}$$

where $p_{c,q}(a)$ is the human response proportion for answer option a. Ties in top-1 answers and modal answers are resolved deterministically by the smallest numeric answer label when available, and otherwise by lexicographic order. We then define the sphere-level modal answer as

$$m_{s,q} = \text{mode}\{y_{c,q} : c \in \mathcal{C}_s\}. \tag{20}$$

Finally, the within-sphere consensus score is

$$\kappa(s,q) = \frac{1}{|\mathcal{C}_s|} \sum_{c \in \mathcal{C}_s} \mathbf{1}\{y_{c,q} = m_{s,q}\}. \tag{21}$$

A score of $\kappa(s,q) = 1$ means that all members of the sphere share the same top-1 answer for question q; lower values indicate same-sphere disagreement. We use the median value over all sphere-question pairs as the threshold:

$$\tau = \text{median}\{\kappa(s,q) : s \in \mathcal{S}, q \in \mathcal{Q}\}, \qquad g(s,q) = \begin{cases} \text{High-Consensus}, & \kappa(s,q) \geq \tau, \\ \text{Low-Consensus}, & \kappa(s,q) < \tau. \end{cases} \tag{22}$$

For the 149 selected WVS questions and eight cultural spheres, this gives 1,192 sphere–question pairs. The median is $\tau = 1.0$, so High-Consensus corresponds to unanimous same-sphere top-1 agreement, while Low-Consensus contains all sphere–question pairs with any internal top-1 disagreement. Evaluation is conducted over culture–question pairs: each (c, q) inherits the label of its corresponding sphere–question pair $(s(c), q)$. The same WVS question can therefore be High-Consensus in one sphere and Low-Consensus in another. The split is fixed across all models, prompting methods, and shot counts. Table 15 summarises the resulting split per sphere.

Table 15: Summary of the sphere-question consensus split used in the ablation analysis. Each sphere contributes 149 selected WVS questions; #High and #Low count sphere-question pairs.

Cultural sphere	**#Members**	**Avg. κ**	**Median κ**	**#High**	**#Low**
English-Speaking	6	0.875	1.000	87	62
Protestant Europe	2	0.903	1.000	120	29
Catholic Europe	3	0.868	1.000	97	52
Orthodox Europe	6	0.829	0.833	71	78
Confucian	6	0.810	0.833	60	89
Latin America	6	0.796	0.833	67	82
African-Islamic	6	0.813	0.833	67	82
West & South Asia	6	0.809	0.833	65	84
Total	41	–	–	634	558

F.2 Human–Model Structural Similarity

For a given prompting method we build the model's culture–culture similarity matrix with the same measure used for the human reference in Appendix D.1, and we read two metrics from it. The within-/between-sphere ratio applies $\mathrm{Within}(g)$ and $\mathrm{Between}(g)$ to the model matrix instead of the human one, so a larger ratio means the model separates the spheres more sharply. In the main text, we report the absolute gap from the human ratio,

$$\Delta = \left| R_{\text{method}} - R_{\text{human}} \right|, \tag{23}$$

where $R = \mathrm{Within}(g)/\mathrm{Between}(g)$. Smaller Δ indicates that the method's sphere separation is closer to the human reference.

The second metric compares the two matrices directly. Writing $s^{\mathrm{H}}(c_i, c_j)$ and $s^{\mathrm{M}}(c_i, c_j)$ for the human and model similarity of a pair of cultures, we collect the upper-triangle entries of both matrices into vectors and take their Spearman rank correlation,

$$\rho_{\mathrm{HM}} = \mathrm{Spearman}\big(\{s^{\mathrm{H}}(c_i, c_j)\}_{i<j},\ \{s^{\mathrm{M}}(c_i, c_j)\}_{i<j}\big). \tag{24}$$

Only the ranking of culture pairs matters, so $\rho_{\mathrm{HM}} = 1$ means the model orders every pair exactly as humans do, and values near zero mean the two orderings are unrelated. For the human reference $\rho_{\mathrm{HM}} = 1$ by definition.

F.3 Closest-Sphere and Prior-Nearest Ratio

The R_{PN} diagnostic of Section 5.3 is defined as follows. We look at all of a culture's responses together and ask which sphere they most resemble. If they align more closely with another sphere than with the culture's assigned one, the culture is not closest to its prior sphere—a pattern that can arise even in human data for cultures near a sphere boundary.

The definition of $\mathrm{align}(c, s)$ depends on the benchmark. For **WVS**, we build a leave-one-out *sphere mode* $m^{-c}_{s,q} = \mathrm{mode}_{c' \in \mathcal{C}_s,\, c' \neq c}\ y_{c',q}$ for each sphere s and question q, the sphere's modal top-1 answer with the target culture removed. The alignment of c with s is the fraction of questions on which c's predicted answer matches that mode:

$$\mathrm{align}_{\mathrm{WVS}}(c, s) = \frac{1}{|\mathcal{Q}|} \sum_{q \in \mathcal{Q}} \mathbf{1}\big[\hat{a}_\theta(q, c) = m^{-c}_{s,q}\big].$$

For **VSM**, we build a leave-one-out sphere centroid $\bar{\mathbf{v}}_s^{-c} = \frac{1}{|\mathcal{C}_s \setminus \{c\}|} \sum_{c' \in \mathcal{C}_s \setminus \{c\}} \mathbf{v}_{c'}$ from the Hofstede 6-D vectors, and define alignment as the normalized similarity:

$$\mathrm{align}_{\mathrm{VSM}}(c, s) = 1 - \frac{\|\mathbf{v}_{\theta,c} - \bar{\mathbf{v}}_s^{-c}\|_2}{100\sqrt{6}}.$$

The *closest sphere* is $\mathrm{closest}(c) = \arg\max_s \mathrm{align}(c, s)$. To measure how far a culture has drifted, the *prior-nearest ratio* compares its alignment with the prior sphere against the closest non-prior sphere,

$$R_{\mathrm{PN}}(c) = \frac{\mathrm{align}(c, s(c))}{\max_{s \neq s(c)} \mathrm{align}(c, s)},$$

so $R_{\mathrm{PN}} > 1$ means the culture stays closest to its own sphere and $R_{\mathrm{PN}} < 1$ means it has drifted to another. For model outputs we take the closest sphere per model and report the majority vote.

G Sphere-Aware Fine-Tuning Details

Algorithm 1 states the two-stage procedure of Section 6.1 in full. We generate all training data with the CulturePark framework (Li et al., 2024b), which expands the 50 WVS seed questions $\mathcal{Q}$ into natural-language samples through multi-agent debate, following the 50-seed setting of CultureLLM (Li et al., 2024a). Sphere statistics are computed only from the non-held-out cultures, so no held-out target's own answers enter training at any stage. The consensus score $\kappa(s, q)$ is defined as in Section 5.2, but the denominator uses $|\mathcal{C}_s \setminus \mathcal{L}|$ rather than $|\mathcal{C}_s|$ to exclude held-out members. For the DPO filtering step, we set $\tau = 0.5$, matching Section 6.1. Appendix E.3 specifies the corresponding pseudo-label substitution in the held-out SC-ICL prompting baseline.

Algorithm 1 Sphere-Aware Fine-Tuning without Target-Specific Data

Require: cultures $\mathcal{C}$ in spheres $\{\mathcal{C}_s\}$, split into held-out low-resource $\mathcal{L}$ and non-held-out $\mathcal{C} \setminus \mathcal{L}$; human top-1 answers $\{y_{c,q}\}$ for $c \in \mathcal{C} \setminus \mathcal{L}$ on the 50 WVS seed questions $\mathcal{Q}$; base model θ_0; threshold τ

1: **for** each sphere s **do** ▷ statistics use non-held-out members $\mathcal{C}_s \setminus \mathcal{L}$ only
2: $m_{s,q} \leftarrow \mathrm{mode}_{c \in \mathcal{C}_s \setminus \mathcal{L}}\, y_{c,q}$; $\kappa(s, q) \leftarrow \frac{1}{|\mathcal{C}_s \setminus \mathcal{L}|} \sum_{c \in \mathcal{C}_s \setminus \mathcal{L}} \mathbf{1}[y_{c,q} = m_{s,q}]$
3: $s^-(s) \leftarrow \arg\max_{s' \neq s} \overline{\mathrm{JS}}(s, s')$ ▷ farthest sphere by mean answer-profile distance
4: **end for**
Stage 1 (SFT-Aug).
5: $\mathcal{D}_{\mathrm{SFT}} \leftarrow \{(T(q, c),\, r^+_{c,q}) : c \in \mathcal{L},\, q \in \mathcal{Q}\}$, where $r^+_{c,q}$ states the consensus answer $m_{s(c),q}$ for c
6: $\theta_{\mathrm{SFT}} \leftarrow \arg\min_\theta \sum_{(x,r) \in \mathcal{D}_{\mathrm{SFT}} \cup \mathcal{D}_{\mathrm{seen}}} -\log p_\theta(r \mid x)$ ▷ $\mathcal{D}_{\mathrm{seen}}$: CulturePark samples of non-held-out cultures
Stage 2 (DPO-Aug).
7: $\mathcal{P} \leftarrow \{(T(q, c),\, r^+_{c,q} \succ r^-_{c,q}) : c \in \mathcal{L},\, \kappa(s(c), q) > \tau\}$, with $r^-_{c,q}$ an answer from a member of $s^-(s(c))$ that differs from $m_{s(c),q}$, localized to c
8: $\theta_{\mathrm{DPO}} \leftarrow \mathrm{DPO}(\theta_{\mathrm{SFT}};\, \mathcal{P} \cup \mathcal{P}_{\mathrm{seen}})$ ▷ $\mathcal{P}_{\mathrm{seen}}$: preference pairs from non-held-out cultures
9: **return** θ_{SFT} (**SFT-Aug**), θ_{DPO} (**DPO-Aug**)

H Full Results

This appendix collects the complete result tables and figures behind the main text, covering significance tests, model-structure diagnostics, and the low-resource breakdowns.

H.1 Statistical Significance

Table 1 treats each model as a replication and asks whether a method would still help on a model we did not evaluate. Here we retain its point estimate—the mean of the ten model-level relative gains—but change the unit used to quantify uncertainty. In each bootstrap replicate, we resample cultures with replacement ($B = 10{,}000$), recompute the relative gain separately for each model, and then average the ten gains. Keeping whole cultures together preserves the correlation among items answered under the same culture-conditioned prompt. The resulting point estimates therefore match the Average row of Table 1, whereas the intervals need not match: the main-table t-intervals measure variation across models, while these cluster-bootstrap intervals measure variation across cultures for the evaluated models. We use the same resampling unit for all three benchmarks; PRISM has only 13

cultures, so its intervals rest on fewer clusters than the others and are correspondingly less reliable. Each interval is an individual 95% interval for one method, and the six are not corrected for multiple comparisons. Both analyses treat the observed model outputs as fixed and therefore do not include variation across decoding runs.

Table 16: Model-level relative gain over Vanilla, with a 95% culture-cluster-bootstrap interval in brackets; **bold** marks an interval that excludes zero. The final row averages the same ten model-level relative gains as Table 1, while its interval is obtained by resampling whole cultures (41 for WVS, 37 for VSM, and 13 for PRISM).

Model	WVS				VSM	PRISM
	CSP	Standard ICL	SP-ICL	SC-ICL	CSP	CSP

Reading the per-model intervals is stricter than counting win rates. On WVS, SC-ICL is the only method whose interval excludes zero for all ten models, whereas CSP does so for six and Standard ICL for four; Mistral-Medium-2505 is reliably *worse* under CSP (-3.4, $[-5.4, -1.6]$), and the small negative value for GPT-4o (-0.1) is indistinguishable from zero ($[-1.8, 1.5]$). On PRISM every model has an interval above zero, and on VSM eight of ten do.

Averaging the ten model-level gains, Standard ICL is the only method whose culture-bootstrap interval covers zero, and it is also the only one that adds demonstrations without any sphere information. CSP on WVS gains $+1.5\%$ $[0.7, 2.4]$: small, but separable from zero when uncertainty is measured across cultures, even though the model-level t-interval in Table 1 crosses zero. Naming the sphere therefore helps least on the format that asks for a single categorical answer, not nowhere.

H.2 Prompt Component Ablation

Table 17 repeats the ablation of Figure 4 in tabular form.

Table 17: Structure component ablation on WVS, mean accuracy (%) over the 10 evaluated models, with the absolute gain over **Base** (pp) in parentheses. **Bold** marks the best method within each shot and consensus subset. Appendix E.1 marks each cue in the prompt template.

Shots	Subset	Accuracy				
		Base (SP-ICL)	+SSA	+SSA+SSD	+SSA+CS (SC-ICL)	+SSA+SSD+CS
1-shot	Overall	54.13	57.57 (+3.4)	57.02 (+2.9)	**57.76** (+3.6)	57.25 (+3.1)
	High-Consensus	69.76	73.87 (+4.1)	73.28 (+3.5)	**74.40** (+4.6)	73.79 (+4.0)
	Low-Consensus	38.72	**41.49** (+2.8)	40.98 (+2.3)	41.36 (+2.6)	40.94 (+2.2)
3-shot	Overall	53.54	58.27 (+4.7)	57.93 (+4.4)	**58.51** (+5.0)	58.24 (+4.7)
	High-Consensus	68.47	74.54 (+6.1)	74.15 (+5.7)	**74.67** (+6.2)	74.35 (+5.9)
	Low-Consensus	38.81	42.22 (+3.4)	41.94 (+3.1)	**42.57** (+3.8)	42.35 (+3.5)
5-shot	Overall	53.94	**58.88** (+4.9)	58.65 (+4.7)	58.56 (+4.6)	58.32 (+4.4)
	High-Consensus	68.47	**74.99** (+6.5)	74.62 (+6.2)	74.75 (+6.3)	74.39 (+5.9)
	Low-Consensus	39.61	**42.99** (+3.4)	42.91 (+3.3)	42.60 (+3.0)	42.46 (+2.9)

H.3 Cultural-Sphere Coherence by Model

Tables 18 and 19 report the underlying Within, Between, and Ratio components for Vanilla prompting. Tables 20 and 21 then give the method-by-model results behind Table 3. These quantities are macro-averaged across cultural spheres, and the ratio and ρ_{HM} are defined in Appendix F.2. A pair

of cultures enters the WVS similarity only on questions that every one of the 41 cultures answered in parsable form under the corresponding model and method. For ρ_{HM}, the human matrix is recomputed on that same question subset. The Hofstede 6-D metrics use the same 37 cultures for every model and method.

Table 18: WVS-based cultural-sphere coherence and human-model structural similarity under Vanilla prompting. #Q is the number of the 149 retained questions usable for that model, i.e. answered in parsable form by all 41 cultures.

Source / model	#Q	Within	Between	Ratio	ρ_{HM}
Human	**149**	**0.735**	**0.628**	**1.172**	**1.000**
GPT-4.1	149	0.805	0.736	1.095	0.495
GPT-4o	149	0.846	0.787	1.076	0.580
GPT-5	132	0.774	0.714	1.085	0.438
GPT-5.2	146	0.829	0.793	1.046	0.400
o3	107	0.752	0.729	1.032	0.213
DeepSeek-V3.2	149	0.617	0.591	1.044	0.217
Llama-3.3-70B	149	0.908	0.847	1.071	0.613
Kimi-K2.5	149	0.716	0.623	1.150	0.643
Mistral-Large-3	149	0.819	0.727	1.128	0.570
Mistral-Medium-2505	149	0.868	0.813	1.067	0.572

Table 19: Hofstede 6-D-based cultural-sphere coherence and human-model structural similarity under Vanilla prompting.

Source / model	Within	Between	Ratio	ρ_{HM}
Human	**0.805**	**0.690**	**1.167**	**1.000**
GPT-4.1	0.932	0.919	1.015	0.324
GPT-4o	0.935	0.924	1.012	0.219
GPT-5	0.894	0.876	1.020	0.258
GPT-5.2	0.936	0.927	1.010	0.113
o3	0.916	0.909	1.008	0.217
DeepSeek-V3.2	0.889	0.891	0.999	0.109
Llama-3.3-70B	0.963	0.947	1.018	0.202
Kimi-K2.5	0.940	0.915	1.027	0.365
Mistral-Large-3	0.953	0.940	1.013	0.350
Mistral-Medium-2505	0.949	0.932	1.019	0.208

Table 20: WVS method-by-model structural results. Panel (a) reports the raw Within/Between ratio and Panel (b) reports ρ_{HM}. The Average rows are arithmetic means of the ten unrounded model-level statistics and reproduce Table 3; the bracketed Δ values are computed from the averaged ratios and the human ratio (1.172), not by averaging model-level absolute gaps. For each model–method pair, both model and human matrices use the questions answered in parsable form by all 41 cultures. All pairs use 149 questions except Vanilla for GPT-5, GPT-5.2, and o3 (132, 146, and 107), and Standard ICL for GPT-5, GPT-5.2, and o3 (145, 142, and 145). Bold in the Average rows matches the corresponding best result in Table 3.

Model	Vanilla	CSP	Standard ICL	SP-ICL	SC-ICL
(a) Within/Between ratio					
GPT-4o	1.076	1.175	1.093	1.144	1.205
GPT-4.1	1.095	1.197	1.112	1.182	1.249
GPT-5	1.085	1.180	1.100	1.155	1.210
GPT-5.2	1.046	1.135	1.043	1.112	1.197
o3	1.032	1.154	1.079	1.155	1.225

Mistral-Medium-2505	1.019	1.047	0.208	0.513
Llama-3.3-70B	1.018	1.025	0.202	0.333
Average	1.014 [Δ0.153]	**1.036 [Δ0.131]**	0.236	**0.381**

H.4 Model Performance

Tables 22 and 23 report model performance on the two datasets, under the same protocol as the Vanilla columns of Table 1. For WVS, performance is strict Top-1 accuracy: a model is correct when its predicted option matches the most frequent human answer for the corresponding culture and question, as described in Appendix C.3. An item the model leaves unanswered or returns in an unparsable form counts as incorrect, so the denominator is always the full set of 149 retained questions; the Answered column reports how many of them each model actually returned, averaged

over cultures. Accuracy is computed per culture and then macro-averaged over the 41 cultures. For Hofstede 6-D, performance is the normalized Euclidean similarity of Appendix C.4, rescaled to a percentage and macro-averaged over the 37 cultures of Table 10. Higher values indicate better agreement with the human reference.

Table 22: WVS performance measured by strict Top-1 accuracy against culture-level human majority answers. Answered is the mean number of the 149 retained questions returned in parsable form per culture; unanswered items count as incorrect.

Rank	Model	Acc. (%)	Answered
1	GPT-4o	55.77	149.00
2	GPT-4.1	53.99	149.00
3	Mistral-Large-3	53.89	149.00
4	GPT-5.2	53.36	148.90
5	GPT-5	53.23	147.98
6	Llama-3.3-70B	52.45	149.00
7	DeepSeek-V3.2	51.37	149.00
8	o3	51.24	146.34
9	Kimi-K2.5	49.55	149.00
10	Mistral-Medium-2505	47.65	149.00

Table 23: Hofstede 6-D performance measured by normalized Euclidean similarity to human score vectors.

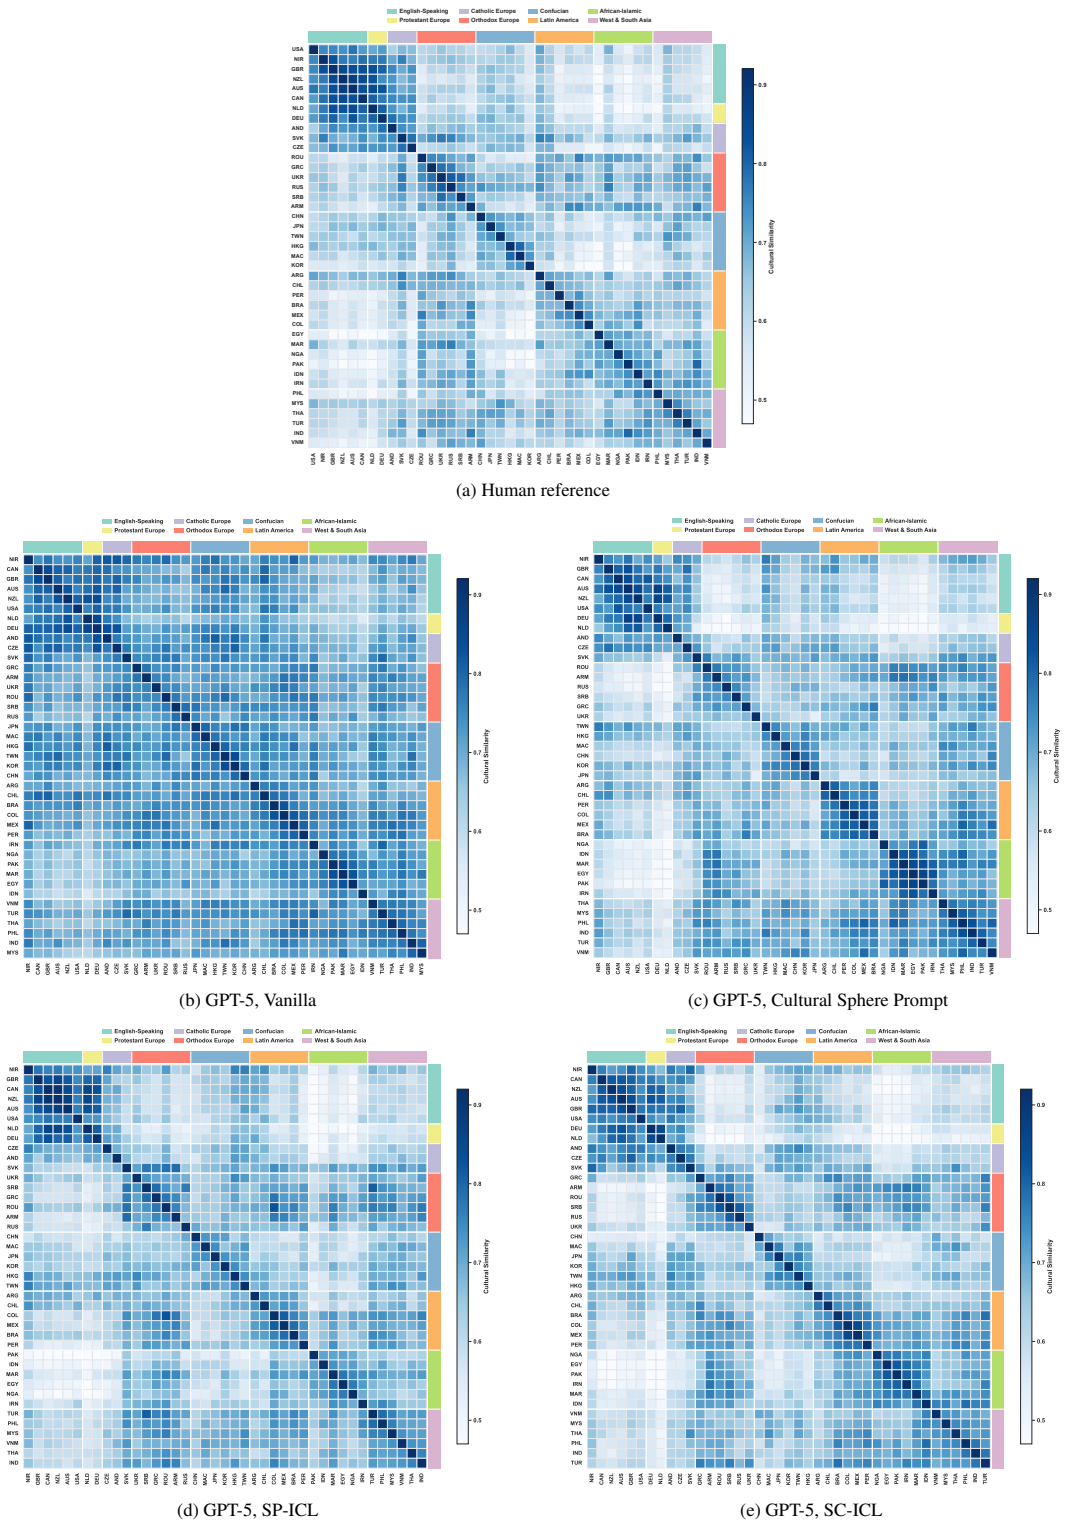
Rank	Model	Similarity (%)
1	Mistral-Large-3	77.33
2	Kimi-K2.5	77.16
3	Mistral-Medium-2505	76.15
4	GPT-5.2	76.13
5	GPT-5	75.85
6	o3	75.56
7	DeepSeek-V3.2	74.78
8	Llama-3.3-70B	74.26
9	GPT-4.1	72.93
10	GPT-4o	72.90

H.5 Structural Case Study

Figure 12 compares the WVS human culture–culture similarity matrix with GPT-5 similarity matrices under different prompting methods. Cultures are ordered by the predefined cultural spheres. The case study visualizes whether cultural-sphere prompting and ICL recover the block structure of the human reference matrix.

H.6 Model-Induced Cultural Similarity Heatmaps

Figures 13 and 14 show culture–culture similarity matrices for six representative models under the country-only prompt, with cultures ordered by cultural sphere. They are the per-model counterpart of the averaged structure metrics in Tables 18 and 19.



(a) Human reference

(b) GPT-5, Vanilla

(c) GPT-5, Cultural Sphere Prompt

(d) GPT-5, SP-ICL

(e) GPT-5, SC-ICL

Figure 12: Structural case study on WVS using GPT-5. Each panel shows a culture–culture similarity matrix with cultures ordered by cultural sphere. The comparison highlights how different prompting methods affect recovery of the human cultural-sphere similarity structure.

H.7 Closest-Sphere Assignments

Table 24 gives the individual prior-nearest ratios behind Figure 5b, and Table 25 reports the discrete closest-sphere assignments corresponding to the same diagnostic in Section 5.3.

Table 24: Prior-nearest ratio R_{PN} for the low-resource group, averaged over 10 models. On VSM the alignment is the normalized similarity to the leave-one-out human sphere centroid, so the two blocks share a direction but not a scale; MAC and AND have no Hofstede scores.

Data	Method	MAR	PAK	PHL	PER	EGY	NGA	MAC	AND	Mean
WVS	Human	0.942	1.083	0.991	1.010	1.000	1.075	1.125	0.947	1.022
	Vanilla	0.857	0.984	0.891	0.886	0.907	0.891	0.863	0.954	0.904
	+SC-ICL	0.993	1.023	0.972	0.965	0.962	0.970	0.986	0.965	**0.979**
	Δ	+0.136	+0.039	+0.081	+0.079	+0.055	+0.079	+0.123	+0.011	+0.075
VSM	Human	1.074	1.113	1.051	0.997	1.072	0.911	–	–	1.036
	Vanilla	0.880	0.906	1.005	0.886	0.894	0.852	–	–	0.904
	+CSP	0.896	0.908	1.041	0.919	0.917	0.884	–	–	**0.928**

Table 25: Closest-sphere assignments for the eight members of the low-resource group. The gray subscript gives the majority-vote count across 10 models; **bold** marks a match to the prior sphere of the group member and † a tie broken alphabetically.

Culture	Prior	Human	Vanilla	+SC-ICL
MAR	AfrI	OrtE	$\mathrm{LatA}_{4/10}$	**AfrI**$^{\dagger}{}_{4/10}$
PAK	AfrI	**AfrI**	**AfrI**$_{5/10}$	**AfrI**$_{9/10}$
PHL	WSA	AfrI	$\mathrm{EngS}_{8/10}$	$\mathrm{AfrI}_{4/10}$
PER	LatA	**LatA**	$\mathrm{EngS}_{6/10}$	$\mathrm{OrtE}_{5/10}$
EGY	AfrI	**AfrI**†	$\mathrm{LatA}_{5/10}$	$\mathrm{LatA}_{7/10}$
NGA	AfrI	**AfrI**	$\mathrm{EngS}_{5/10}$	$\mathrm{LatA}_{7/10}$
MAC	Conf	**Conf**	$\mathrm{ProE}_{7/10}$	**Conf**$^{\dagger}{}_{4/10}$
AND	CatE	ProE	$\mathrm{EngS}_{6/10}$	$\mathrm{EngS}_{5/10}$
Matches		**5/8**	1/8	**3/8**

Abbreviations: EngS = English-Speaking, ProE = Protestant Europe, CatE = Catholic Europe, OrtE = Orthodox Europe, Conf = Confucian, LatA = Latin America, AfrI = African-Islamic, WSA = West & South Asia.

H.8 Results by Resource Group

Tables 26 and 27 separate the two benchmarks by high- and low-resource groups, with absolute gains computed against the corresponding Vanilla score within the same resource group. The VSM split covers 8 high-resource and 6 low-resource cultures, and on WVS the gains are shown only for SC-ICL to keep the high/low comparison readable.

Table 26: VSM normalized Euclidean similarity (%) by resource group. Parentheses give the absolute gain over Vanilla (pp). For each group, bold similarity marks the better result; within CSP, bold gain marks the larger improvement for the same model.

Model	Vanilla		CSP	
	High	Low	High	Low
GPT-4o	77.07	67.27	**79.19** (+2.1)	**70.18** (**+2.9**)
GPT-4.1	77.20	67.91	**80.54** (+3.3)	**74.24** (**+6.3**)
Mistral-Large-3	81.38	72.16	**81.53** (+0.2)	**72.89** (**+0.7**)
GPT-5.2	79.25	71.70	**80.97** (+1.7)	**74.23** (**+2.5**)
GPT-5	81.14	70.54	**84.32** (+3.2)	**74.93** (**+4.4**)
Llama-3.3-70B	75.80	71.35	**78.34** (**+2.5**)	**72.58** (+1.2)
DeepSeek-V3.2	77.15	68.61	**79.98** (+2.8)	**71.91** (**+3.3**)
o3	80.14	70.81	**82.20** (+2.1)	**76.54** (**+5.7**)
Kimi-K2.5	80.90	73.56	**83.02** (+2.1)	**76.71** (**+3.2**)
Mistral-Medium-2505	78.33	71.09	**80.32** (+2.0)	**75.34** (**+4.3**)
Average	78.84	70.50	**81.04** (+2.2)	**73.96** (**+3.5**)

Table 27: WVS accuracy (%) by resource group across all prompting methods. For each group, bold accuracy marks the best absolute score. For SC-ICL, parentheses give the absolute gain over Vanilla (pp); the bolded gain marks the larger improvement for the same model.

Model	Vanilla		CSP		Standard ICL		SP-ICL		SC-ICL	
	High	Low	High	Low	High	Low	High	Low	High	Low
GPT-4o	59.98	53.27	59.14	54.78	60.40	55.03	59.90	55.20	**64.93** (+5.0)	**60.74** (**+7.5**)
