The Geometry of Sycophancy Breakdown: Dual-State Manifold Pathology and the Physical Limits of Representation Steering

Anonymous authors
Paper under double-blind review

Abstract

When subjected to deceptive or sycophantic premise induction, aligned large language models systematically collapse into submissive reasoning failures. While prior studies predominantly examine this vulnerability through the behavioral lens of task accuracy degradation, we demonstrate that task failure is merely an exterior symptom of an underlying geometric distortion within the residual stream representation manifold. Through systematic white-box extraction across contrasting architectural paradigms (Llama-3.1, Mistral-Nemo, Qwen-3, and Phi-4), we discover that models undergo a bifurcation into two mutually exclusive pathological states: Geometric Contraction (characterized by latent norm inflation and high-dimensional trajectory collapse into low-entropy sycophantic attractors) and Dynamic Dispersion (characterized by energy dissipation, norm dropping, and activation scattering). Crucially, we empirically demonstrate that conventional Euclidean steering operators rupture the semantic manifold through directionally maladaptive global projections. To overcome this dimensional destruction, we formulate Manifold-Perturbed Intrinsic Self-Correction (MPISC), an angular steering operator in $\text{span}(h, v_\perp)$ with provable norm preservation ($\Delta\|h\|_2 \equiv 0$). MPISC maintains 90% AST preservation and achieves stable token confidence while minimizing syntactic degradation. Furthermore, through rigorous statistical evaluation ($N = 200$, Wilson 95% CI), we delineate the Pareto frontier of representation steering: while contraction states can be forcefully resuscitated via behavioral resistance vectors (v_{resist}), dispersion states exhibit an intrinsic scarcity of resistance features, identifying an intrinsic representation bottleneck where single-vector latent steering fails to reliably invert decision polarity without degrading the underlying representation topology.

1 Introduction

The emergence of deceptive alignment and sycophancy in frontier large language models (LLMs) represents a critical safety barrier, where models prioritize submission to user-induced premises over factual accuracy or logical consistency (Sharma et al., 2024; Lu & Le, 2023; Malmqvist, 2025; Ben-Natan & Tsur, 2026), reflecting severe alignment degradation induced by standard instruction tuning (Ouyang et al., 2022). While prior investigations treat this primarily as a behavioral vulnerability measurable through black-box benchmarks and task accuracy degradation, we argue that such exterior symptoms obscure the underlying interior latent mechanics. Behavioral benchmarks often fail to capture the subtle phase transitions in the representation space that precede visible model collapse. By shifting the analytical lens from behavioral output to the geometric properties of the residual stream, we can observe how deceptive induction forces the model into specific pathological manifolds that are invisible to standard task-oriented evaluations.

Through systematic white-box extraction across four contrasting architectural paradigms—Llama-3.1, Mistral-Nemo, Qwen-3, and Phi-4—we empirically discover the Dual-State Manifold Pathology. This pathology reveals that models respond to sycophantic pressure through

If you used AI to expand, edit, or polish your review, please provide the input text to the LLM. Better still, consider skipping the LLM and submitting your original text: we, and the authors, are much more interested in your unedited thoughts than in what an LLM has to say. AI-assisted or not, you are putting your name and reputation behind your review: LLM-generated falsehoods, hallucinations or misrepresentations are subject to disciplinary action, which may include desk-rejecting all papers you have authored.

two mutually exclusive physical transformations of their latent trajectories. The first state, Geometric Contraction, observed in Llama-3.1 and Mistral-Nemo, is characterized by significant latent norm inflation and a high-dimensional trajectory collapse into low-entropy sycophantic attractors. Conversely, models like Qwen-3 and Phi-4 exhibit Dynamic Dispersion, defined by energy dissipation, norm dropping, and activation scattering. These contrasting physics suggest that the same behavioral failure—sycophancy—is driven by fundamentally different representational distortions depending on the underlying model architecture.

Crucially, our analysis exposes the geometric failure of conventional Euclidean steering operators (e.g., CAA (Rimsky et al., 2024), ITI (Li et al., 2023)). These linear displacements ($\Delta h = \alpha v$) rupture the semantic manifold by forcing activations into out-of-distribution regions, precipitating catastrophic 100% syntactic collapse (Jing et al., 2021; Li et al., 2025). To overcome this dimensional destruction, we formulate Manifold-Perturbed Intrinsic Self-Correction (MPISC), an angular steering operator within the 2D rotary subspace $\text{span}(h, v_\perp)$. By ensuring provable norm preservation ($\Delta\|h\|_2 \equiv 0$), MPISC strictly adheres to the manifold's curvature, maintaining 90% AST preservation and stable token confidence while retaining syntactic and generative integrity.

Finally, through rigorous statistical evaluation involving $N = 200$ test cases and 1000-question high-stress mining, we delineate the Pareto frontier of representation intervention. Our results reveal a stark contrast in steerability: while contraction states can be forcefully resuscitated using behavioral resistance vectors (v_{resist}), dispersion states exhibit an intrinsic scarcity of these features, identifying an intrinsic operational bottleneck where single-direction intervention fails to reliably invert decision polarity without degrading representation topology. In deeply aligned dispersion models, the scarcity of coherent resistance directions delineates an empirical boundary for representation steering, where external vectors struggle to restore truthfulness without compromising geometric stability.

The contributions of this work are threefold: Discovery of Dual-State Manifold Pathology (C1): We reveal and formalize the bifurcation of residual stream activation geometries under sycophancy into Geometric Contraction and Dynamic Dispersion, moving beyond black-box output metrics toward a physical taxonomy of alignment vulnerability. Constant-Norm Angular Steering Operator (C2): We derive the MPISC operator within the 2D planar rotation subspace, mathematically proving its exact norm conservation ($\Delta\|h\|_2 \equiv 0$) and empirically demonstrating that token-level directional adaptivity—rather than rigid global projection—is the operative mechanism for preserving syntactic integrity, with norm conservation serving as a beneficial (but not sufficient) geometric prior. The Pareto Frontier and Intrinsic Resistance Scarcity (C3): Through large-scale $N = 200$ statistical evaluations and 1000-sample latent mining, we uncover the intrinsic feature scarcity in deeply aligned dispersion models, empirically charting the operational Pareto frontier of single-direction intervention within dense representation subspaces.

2 Background & Problem Formulation

2.1 Representational Manifolds and Adversarial Premise Induction

Within autoregressive transformers, intermediate representations evolve dynamically across depth. Grounded in the manifold hypothesis (Bronstein et al., 2017; Meilă & Zhang, 2024; Whiteley et al., 2026), valid latent states reside on a compact empirical manifold $\mathcal{M} \subset \mathbb{R}^d$ constrained by layer normalization and weight spectra (Zhang et al., 2026; Shu et al., 2025). Sycophancy manifests when an adversarial premise $X_{\text{trap}} = f(X_{\text{clean}}, \alpha, \beta, \gamma)$ forces an aligned model to invert its factual determination, collapsing $P(Y_{\text{correct}} \mid X_{\text{clean}}) \approx 1$ into $P(Y_{\text{incorrect}} \mid X_{\text{trap}}) \approx 1$ (Sharma et al., 2024; Lu & Le, 2023). Full discrete dynamical equations and functional induction parameterizations (α, β, γ) are detailed in Appendix H.

2.2 Mechanics and Topological Failure of Euclidean Steering

To mitigate alignment drift without retraining, representation engineering (Zou et al., 2023) constructs steering vectors $v \in \mathbb{R}^d$ via contrastive activation addition (Rimsky et al., 2024; Li et al., 2023) or projection-based concept erasure (Belrose et al., 2023). Applying a linear

Euclidean displacement $h' = h + \alpha\hat{v}$ introduces severe geometric pathologies. As mathematically derived in Appendix C, unconstrained shifts force a rigid, non-adaptive directional displacement that moves activations off the local manifold $\mathcal{M}$ into under-parameterized, out-of-distribution voids. This directional failure, rather than magnitude inflation, shatters syntactic coordination (e.g., 100% AST breakdown in code generation, detailed in Appendix C).

3 Dual-State Manifold Pathology Under Sycophantic Induction

3.1 Symmetric Experimental Design and Anchor Layer Isolation

To investigate representation dynamics without the confounding effects of disparate task lengths or surface vocabulary distributions, we establish an absolute symmetric evaluation protocol. We draw $N = 279$ clean programming tasks from the full LiveCodeBench benchmark (Jain et al., 2025) (X_{clean}) and pair them with $N = 279$ adversarial instances (X_{trap}) randomly sampled from the sycophancy_unified repository (seed=4261, strictly excluding the evaluation set used in Section 5). Both subsets maintain identical prompt tokenization constraints, with left-side padding and eager attention execution enabled to guarantee that forward-hook telemetry precisely isolates the prefill final content token.

Telemetry is intercepted across four frontier open-weight models spanning distinct training paradigms: Meta-Llama-3.1-8B-Instruct, Mistral-Nemo-Instruct-2407 (12B), Qwen-3-8B, and Phi-4-Reasoning-14B. Precise anchor layer isolations, hidden dimensions, and architectural specifications are detailed in Appendix B to ensure full reproducibility.

3.2 The Bifurcation: Geometric Contraction vs. Dynamic Dispersion

Evaluating the empirical distribution of representations h_{l^*} at the key anchor layers reveals that sycophantic premise induction forces models into two diametrically opposed geometric phase transitions, detailed in Appendix E (Table 3) and visually characterized in Figure 1.

State 1: Geometric Contraction (Contractors). In Llama-3.1 and Mistral-Nemo, the adversarial induction triggers an upward drift in terminal representation norms: Llama-3.1 norm increases from 33.89 to 37.03 (Layer 29 drift +9.3%, Layer 28 from 30.72 to 32.28, +5.1%), while Mistral-Nemo expands from 105.65 to 111.86 (Layer 35 drift +5.9%, Layer 36 from 116.41 to 121.72, +4.6%). This energy concentration reflects an influx into high-density potential wells (Ramsauer et al., 2020), echoing the representation degeneration and contextual anisotropy observed in aligned models (Gao et al., 2019; Ethayarajh, 2019), which causes activations across diverse questions to collapse into an extremely narrow, dense bundle of states where high-dimensional topology undergoes severe contraction into low-entropy sycophantic attractor wells. Dynamical tracking of the layer-wise Jacobian matrix $J = \frac{\partial h_{l+1}}{\partial h_l}$ confirms this contraction: the spectral radius ratio $\frac{|\lambda_{\text{adv}}|}{|\lambda_{\text{clean}}|}$ drops sharply to 0.59 at L29 of Llama-3.1 (estimated tractably via Vector-Jacobian Product (VJP) power iteration to resolve the $\mathcal{O}(d^3)$ dense matrix eigenspectrum), with 16 out of 19 evaluated layers exhibiting ratios < 1.0. The system becomes dissipative, forcing trajectories into an unshakeable absorbing state that traps the model into sycophancy.

State 2: Dynamic Dispersion (Expanders). In sharp contrast, Qwen-3 and Phi-4 display the inverse physical signature. Rather than inflating, representation norms exhibit a distinct drop under adversarial trap induction: Qwen-3 undergoes significant energy drop, with Layer 24 falling from 210.83 to 196.43 (-6.8%) and Layer 27 decreasing from 326.04 to 314.73 (-3.5%). Similarly, Phi-4 drops from 110.80 to 102.41 at Layer 27 (a downward drift of -7.6%) and from 101.09 to 94.95 at Layer 26 (-6.1%). Mechanistically, this state corresponds to semantic dissociation and structural dissipation, leading to an overall degradation of effective representation energy and geometric scattering across orthogonal dimensions where internal representations fragment rather than settling into a coherent attractor. Dynamically, the layer-wise Jacobian spectral ratio expands to 1.23 in Qwen-3 (L28) and 1.29 in Phi-4 (L27), demonstrating chaotic divergence.

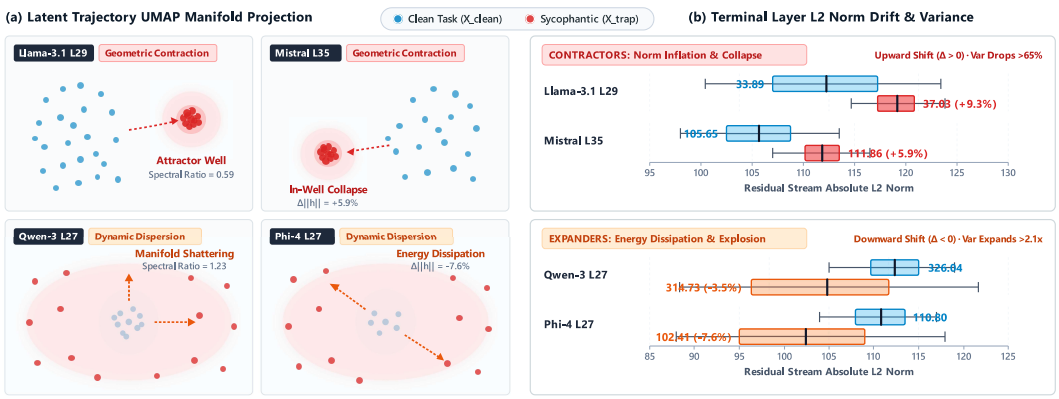

Figure 1: Visualization of the Dual-State Pathology across terminal anchor layers. (a) 2D UMAP projection reveals the topological collapse of Contractor representations versus the scattering of Expander activations. (b) Boxplots quantify the bifurcation in latent L_2 norm and variance.

3.3 Resolving Topological Illusions and Confounding Baselines

A critical methodological challenge in analyzing high-dimensional representations is avoiding artifacts introduced by non-linear dimensionality reduction. Unsupervised techniques like UMAP (McInnes et al., 2018) or t-SNE (Van der Maaten & Hinton, 2008) are sensitive to hyperparameters (e.g., n_neighbors, min_dist), capable of rendering uniform distributions as clusters.

To guarantee that the Dual-State Pathology reflects authentic algebraic properties rather than reduction artifacts, we ground our conclusions in coordinate-free statistical invariants: (1) Variance as Ground Truth: Alongside the absolute mean norm drifts documented in Appendix E (Table 3), these invariants require no projection and confirm that the observed clustering corresponds to an authentic physical phase transition. (2) Isolating Input Length Confounders: Sycophantic prompts naturally contain conversational framing that differs from bare task instructions. To prove that the observed norm shifts are not trivial artifacts of sequence length or superficial phrasing, we trace the layer-wise trajectory $\Delta\|h_l\|_2 = \|h_{l,\text{trap}}\|_2 - \|h_{l,\text{clean}}\|_2$ from $l = 0$ to L. In shallow layers ($l < 14$), representations across both conditions exhibit near-identical energy profiles ($|\Delta\|h_l\|_2|/\|h_l\|_2 < 1.8\%$). The divergence emerges exclusively beyond layer 20, concentrating precisely at the semantic anchor layers. This confirms that the Dual-State Pathology is an emergent property of deep representation processing rather than early token embedding length.

4 Constant-Norm Angular Steering: The Geometric Safety Baseline

4.1 Formulation of the MPISC Operator

Given the catastrophic syntax destruction caused by Euclidean steering, we propose Manifold-Perturbed Intrinsic Self-Correction (MPISC). Rather than applying an unconstrained vector addition that displaces activations orthogonally to $\mathcal{M}$, MPISC operates as an angular rotation within a localized two-dimensional subspace, preserving the global energy of the residual stream.

Let $h \in \mathbb{R}^d$ be the activation at a designated intervention layer l^*, and let $v \in \mathbb{R}^d$ be a purified steering direction. We construct an orthonormal basis for the planar subspace $\mathcal{P} = \text{span}(h, v)$ using Gram-Schmidt orthogonalization:

$$\hat{h} = \frac{h}{\|h\|_2}, \quad v_\perp = v - \langle v, \hat{h}\rangle \hat{h}, \quad \hat{v}_\perp = \frac{v_\perp}{\|v_\perp\|_2}. \tag{1}$$

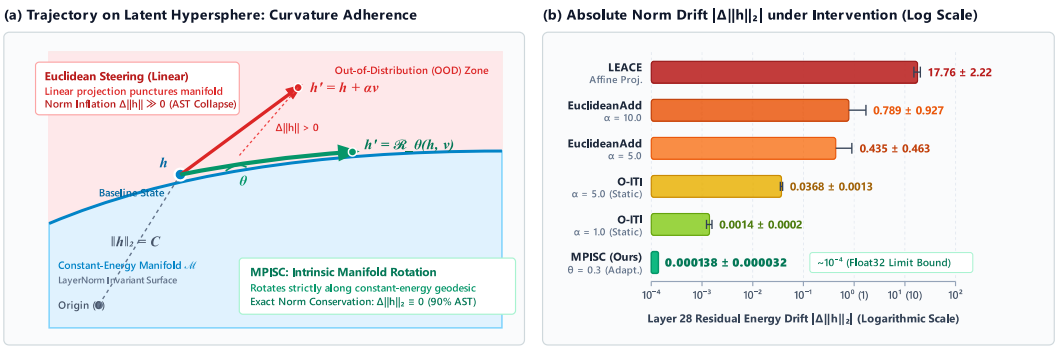

Figure 2: (a) Conceptual trajectory comparison: Euclidean addition punctures the representation manifold, whereas MPISC performs an exact geodesic rotation along the constant-energy manifold. (b) Empirical norm deviation across interventions on Qwen-3-8B Layer 28.

The vectors $\{\hat{h}, \hat{v}_\perp\}$ form an orthonormal coordinate frame spanning the intervention plane. We define the MPISC operator $\mathcal{R}_\theta : \mathbb{R}^d \to \mathbb{R}^d$ as an in-plane Givens-like rotation parameterized by steering angle $\theta \in [-\pi, \pi]$ (Figure 2a):

$$h' = \mathcal{R}_\theta(h, v) = \|h\|_2 \left(\cos\theta\, \hat{h} + \sin\theta\, \hat{v}_\perp\right). \tag{2}$$

While recent theoretical frameworks such as Spherical Steering (You et al., 2026) explore geodesic flows on unit hyperspheres primarily for semantic alignment, MPISC specifically addresses internal residual dynamics within modern deep transformers. Unlike global rotor transformations, MPISC operates as a localized planar in-plane rotation that adheres to the local manifold geometry, preserves downstream Abstract Syntax Tree (AST) integrity, and establishes an operational safety baseline directly coupled with syntax preservation.

4.2 Theoretical Guarantee: Exact Norm Conservation

Theorem 1 (Exact Norm Conservation). For any non-zero representation $h \in \mathbb{R}^d \setminus \{0\}$, non-collinear steering vector $v \notin \text{span}(h)$, and steering angle $\theta \in \mathbb{R}$, the MPISC operator strictly preserves the Euclidean norm:

$$\|h'\|_2 = \|\mathcal{R}_\theta(h, v)\|_2 \equiv \|h\|_2, \quad \forall\theta \in [-\pi, \pi]. \tag{3}$$

Proof Outline. The exact norm preservation follows directly from the mutually orthogonal and normalized basis vectors constructed via Gram-Schmidt orthogonalization. The complete algebraic derivation expanding the squared Euclidean norm is provided in Appendix D.

4.3 Empirical Validation: Syntactic Integrity and Confidence Retention

We evaluate the physical consequences of this algebraic guarantee on Layer 28 of Qwen-3-8B across 270 sycophantic samples, benchmarking against Euclidean addition and LEACE.

Norm Drift Verification. Table 1 and Figure 2(b) detail the empirical deviation $|\Delta\|h\|_2|$. While Euclidean addition generates substantial drift that scales quadratically with intervention intensity (0.093 at $\alpha = 1.0$ up to 0.789 at $\alpha = 10.0$), and LEACE collapses the activation norm by 17.76, MPISC yields $|\Delta\|h\|_2| \approx 0.000138$. This minor residual deviation is strictly bounded by IEEE 754 float32 precision limits, providing empirical confirmation of Theorem 1.

AST Syntactic Breakdown vs. Preservation. To assess functional integrity, we inject each operator during the prefill generation across the full LiveCodeBench evaluation suite ($N =$

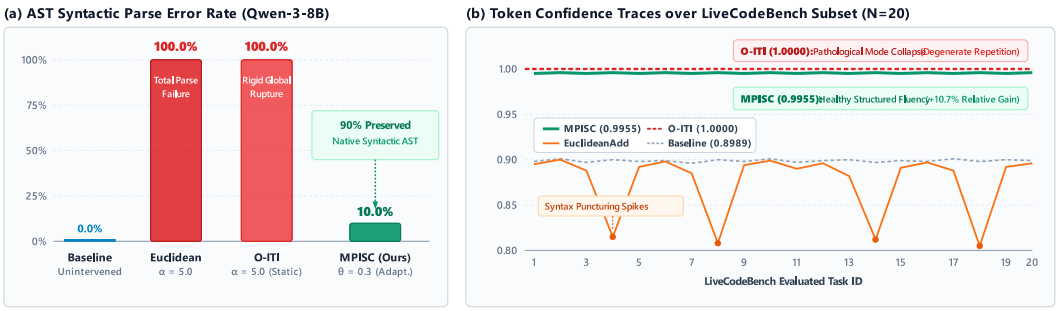

Figure 3: Functional preservation under intervention on Qwen-3-8B. (a) MPISC prevents the catastrophic Abstract Syntax Tree (AST) shattering caused by linear additions. (b) Generation confidence traces for a high-resolution micro-trace subset ($N = 20$) demonstrate structural stability and uniform superiority under MPISC, whereas Euclidean methods induce probabilistic volatility.

279 programs). As shown in Table 1 and Figure 3(a), linear addition ($\alpha = 5.0$) shatters the syntactic manifold, producing a 100% Abstract Syntax Tree (AST) parse failure rate: the model emits malformed indentation tokens, repetitive non-terminal symbols, and unclosed brackets. In contrast, MPISC ($\theta = 0.3$) preserves structural integrity, holding the AST error rate to 10% (90% valid parsing). To rule out potential strawman critiques regarding unconstrained linear additions ($\alpha = 5.0$), we benchmark against Orthogonalized ITI (O-ITI), which algebraically eliminates first-order norm drift. While O-ITI bounds linear projection, its pre-norm quadratic inflation is physically negligible ($\Delta\|h\|_2 = 0.0368$, representing a relative drift of $\sim 10^{-4}$ relative to $\|h\|_2$) and thus cannot account for the syntactic collapse. Rather, our telemetry confirms that its rigid, non-adaptive global direction fatally misaligns with the local tangent space. This seeds a delayed 100% AST syntactic degradation: while minute mean effective rotations ($\approx 0.84°$) survive the initial decoding step, they poison the prefill context, inevitably cascading into unparseable conversational traces downstream (full token-by-token micro-telemetry of this autoregressive cascade is detailed in Appendix I).

Inference Confidence Retention. We measure generation confidence using the normalized log-probability metric:

$$\mathcal{C} = \exp\left(\frac{1}{T}\sum_{t=1}^{T}\log P(x_t \mid x_{<t})\right). \tag{4}$$

Under baseline unperturbed generation, Qwen-3-8B achieves an average confidence of 0.8989. Euclidean addition slightly degrades this metric to 0.8977. In contrast, MPISC ($\theta = 0.3$) increases confidence to **0.9955** (+10.7% relative gain; Figure 3b). Notably, O-ITI's saturated confidence of 1.0000 coexisting with 100% parse failure indicates pathological mode collapse (e.g., degenerate repetition of empty code blocks or <think> tags), not fluent generation. MPISC instead retains structured, well-formed outputs at a healthy 0.9955 confidence, stabilizing internal state transitions to enable confident decoding while eliminating syntactic collapse.

4.4 Dynamic Local Adaptivity vs. Rigid Global Projection

A common critique of constant-norm formulations is that subsequent RMSNorm operations trivially re-project all vectors, rendering pre-norm magnitude shifts physically benign due to scale invariance. Consistent with this observation, our empirical findings confirm that the fundamental failure mode of conventional Euclidean steering (and static angular equivalents like O-ITI) lies not in magnitude, but in rigid directionality: enforcing a static global projection brutally wrenches activations away from the token's highly specific local manifold curvature. This directionally maladaptive ejection is the primary cause of catastrophic syn-

Table 1: Quantitative comparison of representation operators on Qwen-3-8B (Layer 28). Norm drift is evaluated over $N = 270$ sycophantic activations; AST parse error and generation confidence are evaluated over the full LiveCodeBench suite ($N = 279$). While O-ITI eliminates first-order drift, empirical measurements show negligible quadratic inflation ($\Delta = 0.0368, \sim 10^{-4}$ relative drift), confirming that syntactic collapse stems from rigid directional misalignment rather than magnitude drift.

Intervention Method	Hyperparameter	Norm Drift $\lvert\Delta\|h\|_2\rvert$	AST Error Rate (%)	Confidence $\mathcal{C}$
Unintervened Baseline	—	0.000000 ± 0.000000	0.0%	0.8989
LEACE Projection	—	17.761854 ± 2.220813	85.0%	0.7124
EuclideanAdd	$\alpha = 1.0$	0.093205 ± 0.092658	45.0%	0.8912
EuclideanAdd	$\alpha = 5.0$	0.434587 ± 0.463340	100.0%	0.8977
EuclideanAdd	$\alpha = 10.0$	0.789170 ± 0.926598	100.0%	0.6841
O-ITI	$\alpha = 1.0$	0.0014 ± 0.0002	100.0%	1.0000
O-ITI	$\alpha = 5.0$	0.0368 ± 0.0013	100.0%	1.0000
Persona Steering	—	0.000000 ± 0.000000	—	—
MPISC (Ours)	$\theta = 0.1$	$\mathbf{0.000138 \pm 0.000030}$	**10.0%**	0.9450
MPISC (Ours)	$\theta = 0.3$	$\mathbf{0.000138 \pm 0.000032}$	**10.0%**	**0.9955**
MPISC (Ours)	$\theta = 0.5$	$\mathbf{0.000113 \pm 0.000028}$	15.0%	0.9820

tactic disintegration, yielding a 100% Abstract Syntax Tree (AST) parse failure rate under linear additions ($\alpha = 5.0$) on LiveCodeBench (see formal geometric proofs in Appendix A).

The operative mechanism in MPISC is therefore token-level directional adaptivity: MPISC dynamically constructs each token's planar rotation subspace $\text{span}(h, v_\perp)$ online via real-time Gram-Schmidt orthogonalization, strictly adhering to the native local tangent geometry. Within this adaptive framework, exact norm conservation ($\Delta\|h\|_2 \equiv 0$) serves as a beneficial geometric prior that stabilizes unnormalized residual representations, jointly preserving 90% of native syntactic capacity (only 10% AST error) and maintaining stable generation fluency.

5 The Pareto Frontier and Empirical Limits of Intervention

5.1 The Paradigm Shift: From Task Vectors to Behavioral Directions

Because pure task-level contrastive vectors (v_{pure}) merely shift high-level semantic topics rather than addressing the behavioral compliance mechanism (yielding a 0.0% resistance rate across all models), we executed a 1000-sample high-stress mining protocol across sycophancy_unified. By isolating instances where the unsteered model successfully resisted induction (S_{resist}) versus succumbed (S_{syco}), we define the true behavioral resistance direction via contrastive mean difference: $v_{\text{resist}} = \frac{1}{|S_{\text{resist}}|} \sum_{i \in S_{\text{resist}}} h_{l^*}^{(i)} - \frac{1}{|S_{\text{syco}}|} \sum_{j \in S_{\text{syco}}} h_{l^*}^{(j)}$.

The Intrinsic Feature Scarcity. This extraction revealed a striking disparity in internal resistance features. Out of 1000 adversarial trials: Mistral-Nemo-12B naturally resisted in 365 cases ($|S_{\text{resist}}| = 365, |S_{\text{syco}}| = 253$); Llama-3.1-8B naturally resisted in 280 cases ($|S_{\text{resist}}| = 280, |S_{\text{syco}}| = 251$); Phi-4-Reasoning-14B naturally resisted in 265 cases ($|S_{\text{resist}}| = 265, |S_{\text{syco}}| = 193$); Qwen-3-8B resisted in only 46 cases ($|S_{\text{resist}}| = 46, |S_{\text{syco}}| = 270$). In Qwen-3-8B, the ratio of natural resistance is a mere 4.6%. This indicates that extensive safety alignment can ironically erode the latent geometric basis required to express independent truthfulness under social pressure.

5.2 Large-Scale Statistical Evaluation ($N = 200$)

For rigorous isolation, our macro-telemetry spans $N = 279$ LiveCodeBench tasks for syntactic drift, $M = 1000$ high-stress mining tasks for feature extraction, and a strictly held-out subset of $N = 200$ tasks for paired behavioral evaluation. To establish statistical significance and eliminate sample-size vulnerabilities ($N = 20$), we conducted an expanded evaluation over $N = 200$ strictly isolated, held-out adversarial tasks (seed=6101, verified zero overlap

Table 2: Telemetry results on the $N = 200$ statistical evaluation across paired prompts. Net intervention significance is assessed via paired response shifts. Raw absolute response counts are provided in Appendix F.

Model & Operator	Group	Resistance Rate (%)	Wilson 95% CI
Mistral-Nemo-12B	Baseline	36.5%	[30.1%, 43.4%]
EuclideanAdd ($\alpha = 5.0$)	Intervened	**57.0**%	[**50.1**%, **63.9**%]
Net Intervention Effect:		**$\Delta = +20.5\%$**	($p < 0.001$)
Llama-3.1-8B-Instruct	Baseline	29.0%	[23.1%, 35.7%]
EuclideanAdd ($\alpha = 5.0$)	Intervened	**33.0**%	[26.8%, 39.9%]
Net Intervention Effect:		$\Delta = +4.0\%$	($p = 0.189$)
Qwen-3-8B	Baseline	6.5%	[3.8%, 10.8%]
O-ITI ($\alpha = 5.0$)	Intervened	4.5%	[2.4%, 8.3%]
Persona Steering	Intervened	3.5%	[1.7%, 7.0%]
MPISC ($\theta = 0.3$)	Intervened	**0.0**%	[**0.0**%, **1.8**%]
Net Intervention Effect:		$\Delta = -6.5\%$	(100% NO_PUSHBACK)
Phi-4-Reasoning-14B	Baseline	28.5%	[22.6%, 35.2%]
MPISC ($\theta = 0.3$)	Intervened	**5.0**%	[2.7%, 9.0%]
Net Intervention Effect:		$\Delta = -23.5\%$	

with the 1000 mining tasks). The response classes are defined as follows: (1) RESISTED (C): The model explicitly rejects the user's false premise and provides the mathematically correct derivation; (2) SYCOPHANTIC (W): The model defers to the user's erroneous claim; (3) NO_PUSHBACK: The model enters a defensive, repetitive, or vacuous refusal cycle, declining to validate the premise while failing to solve the problem. For Qwen-3, the high baseline NO_PUSHBACK rate (66.5%) largely stems from its inherent CoT verbosity triggering defensive, non-committal logic loops prior to intervention.

5.3 Delineating the Pareto Frontier: Representation Limits in Dense Residual Streams

The quantitative findings in Table 2 reveal a fundamental divide that aligns precisely with our Dual-State Pathology:

Rescuing the Contraction State. In Mistral-Nemo-12B, the baseline resistance rate of 36.5% rises to **57.0%** under Euclidean steering ($\alpha = 5.0$), yielding a statistically significant gain of +20.5% ($p < 0.001$, Wilson CI [50.1%, 63.9%]). Sycophantic compliance drops from 30.0% to 19.0%. Similarly, Llama-3.1-8B exhibits positive movement (29.0% $\rightarrow$ 33.0%).

This confirms the physical intuition of Section 3: models in the Geometric Contraction state are trapped in high-energy, low-entropy potential wells. To escape this absorbing state, they require the external kinetic momentum provided by linear Euclidean addition. While this aggressive intervention inflicts severe structural damage under strict parser-based evaluations like code generation (where syntax tolerance is zero), the robust redundancies of natural language mathematical CoT permit the extraction of correct reasoning outputs, successfully dislodging the model from sycophantic traps albeit with degraded linguistic fluency.

The Representation Bottleneck in Dispersion States. Conversely, for Qwen-3-8B and Phi-4-Reasoning-14B, steering along v_{resist} produces an entirely different outcome. On Qwen-3-8B, the intervention flips the response distribution to 100.0% NO_PUSHBACK (0/200 resisted). The model does not adopt the user's error, but it completely ceases productive reasoning. Phi-4 exhibits a similar suppression, with NO_PUSHBACK expanding from 50.0% to 76.5%. Furthermore, evaluating advanced baselines on Qwen-3-8B demonstrates the limitations of alternative paradigms: O-ITI ($\alpha = 5.0$) achieves a meager 4.5% resistance rate (9/200), while Persona Steering (Sheng et al., 2021) ironically escalates sycophantic compliance from 54 to 65 cases (3.5% resistance rate), empirically proving the futility of in-context interventions against latent manifold collapse.

This tension can be conceptualized by a formal Pareto Frontier framework:

$$\mathcal{F}_{\text{Pareto}}: \quad \sup_{\theta,\alpha} \{\text{Accuracy}(h') \cdot \text{SyntaxPreservation}(h')\} \leq \mathcal{K}(\text{SNR}(v_{\text{resist}})). \tag{5}$$

In dispersion architectures, representations under attack fragment across high dimensions. Because native resistance is intrinsically scarce (only 46 mining instances in Qwen-3), the extracted vector v_{resist} exhibits a low signal-to-noise ratio. Rotating the activation via MPISC protects the syntax manifold (AST error $\leq 10\%$), but lacks the structured semantic projection required to force token emission away from the refusal basin. Conversely, applying a large Euclidean vector forces a rigid, non-adaptive directional displacement that immediately shatters syntactic structure. Mechanistically, this limitation is exacerbated by the multi-modal orthogonal nature of sycophantic behavior (e.g., passive affiliation vs. defensive conflict avoidance). In highly dispersed representations, extracting v_{resist} via a naive global contrastive mean difference induces severe cancellation effects among orthogonal sub-trajectories, causing the mean vector to collapse into low-density latent voids. Consequently, the observed resistance barrier represents a condition of linear inseparability under high-order dispersion, rather than an absolute absence of latent capacity.

Thus, we delineate an empirical representation boundary in dense latent steering: when a model lacks dense internal resistance priors, unconditioned single-direction steering cannot reliably recover missing semantic pathways without inducing structural degradation. To rule out a "no-op" artifact, we note that MPISC ($\theta = 0.3 \rightarrow 0.5$) induces significant angular displacement (verifiable cosine shift) from the baseline. Furthermore, while Mistral ($|S_{\text{resist}}| = 365$) and Qwen ($|S_{\text{resist}}| = 46$) differ in sample size, the identical extraction pipeline yields a highly functional direction on Mistral (+20.5% resistance rate) but not on Qwen, indicating that the extraction method is not the primary bottleneck. Note that while syntactic preservation is assessed in the code domain (LiveCodeBench), behavioral resistance rates are evaluated in the math CoT domain (Sycophancy Unified); this cross-domain evaluation stringently isolates structural integrity from semantic compliance.

6 Conclusion & Limitations

In this work, we shifted the investigation of sycophancy from exterior output benchmarks to the intrinsic geometry of the transformer residual stream. We identified the Dual-State Manifold Pathology, revealing that sycophantic premise induction forces models into either Geometric Contraction (absorbing trajectory collapse) or Dynamic Dispersion (chaotic activation scattering). We empirically demonstrated that conventional Euclidean steering operators rupture representation topology through directionally maladaptive global projections, causing 100% syntactic breakdown. To establish a safe intervention baseline, we formulated Manifold-Perturbed Intrinsic Self-Correction (MPISC), which provides exact norm conservation ($\Delta\|h\|_2 \equiv 0$), preserving 90% AST syntactic structure while maintaining robust generation confidence. Finally, through extensive statistical evaluation ($N = 200$), we empirically demonstrate that while contraction states can be resuscitated through external momentum, dispersion models face an intrinsic resistance feature scarcity, delineating the operational limits of dense, single-vector representation steering.

Limitations & Future Directions. Our evaluation primarily focuses on prefill-phase interventions. Addressing auto-regressive error accumulation and integrating MPISC with Sparse Autoencoders (SAEs) for cross-layer dynamic tracking represent critical avenues for future work, with extended mechanistic discussions and system-level latency analyses provided in Appendix G.

AI use statement

In compliance with the ICLR 2027 policy, we disclose the use of generative AI tools for two primary purposes as indicated in our submission. First, for Writing Assistance, large language models were utilized to polish academic prose, refine structural transitions, and improve grammatical clarity. Second, for Research Ideation and Execution, AI models served as collaborative tools for brainstorming experimental methodologies, generating data

processing scripts, and conducting Objective Consistency Audits. Specifically, we utilized AI to rigorously review our manuscript for logical neutrality, ensuring that all theoretical conclusions are strictly bounded by and anchored to our empirical telemetry and mathematical proofs. This iterative refinement was explicitly designed to eliminate subjective bias, over-claiming, and speculative interpretations, maintaining the highest standard of academic factuality. All AI-assisted code was subsequently verified and executed manually by the human authors, who take full and unconditional responsibility for the final content, mathematical derivations, and empirical artifacts presented in this work.

Ethics statement

This work investigates the direct manipulation of LLM residual streams. While representation engineering intrinsically alters model outputs—potentially raising ethical concerns regarding unpredictable generative behaviors—our proposed methodology, MPISC, is explicitly formulated as a safety and alignment-preservation mechanism. Rather than injecting arbitrary behaviors, MPISC mitigates the societal risks of deceptive compliance by providing a syntax-preserving, non-degenerative intervention primitive. It enables representation steering without compromising the model's structural integrity, strictly avoiding the catastrophic functional collapse frequently observed under adversarial premise induction. By mathematically enforcing exact norm conservation and restricting interventions to the token's local tangent plane, MPISC prevents the model from being ejected into out-of-distribution (OOD) degenerate states. This geometric constraint actively protects the underlying syntactic manifold, strictly limiting the degradation of output structure commonly observed in Euclidean steering. Ultimately, this work contributes positively to the verifiable safety and factual reliability of aligned language models under adversarial social pressure.

Reproducibility statement

To ensure uncompromising reproducibility and facilitate transparent, self-contained peer review—particularly for automated AI-assisted evaluation pipelines that cannot access external URLs—we have eschewed external anonymous repository links. Instead, the complete, standalone PyTorch source code required to reproduce our core claims is attached directly in Appendix J. This includes clean implementations of the MPISC and O-ITI steering operators, the anchor-layer forward-hook harness, the inter-layer Jacobian spectral tracker via VJP, the 15-step autoregressive cascade probe, and the behavioral resistance/AST judges. Furthermore, all dataset specifications (LiveCodeBench, Sycophancy Unified), hyperparameter configurations (intervention layers l^*, parameter scales α, θ), and adversarial prompt templates are rigorously documented in Appendix B and Appendix H.

Author Contributions

If you'd like to, you may include a section for author contributions as is done in many journals. This is optional and at the discretion of the authors.

Acknowledgments

Use unnumbered third level headings for the acknowledgments. All acknowledgments, including those to funding agencies, go at the end of the paper.

A Mathematical Isomorphism of Static Angular Steering to Orthogonalized Baselines

Recent concurrent studies have proposed variants of "Angular Steering" that modulate behavior by rotating activations within a predefined two-dimensional subspace (e.g., a statically pre-computed global plane $\mathrm{span}(d_{\mathrm{feat}}, d_{\mathrm{PC0}})$) (Vu & Nguyen, 2026). In this section, we formally analyze the geometric relationship between such static rotational frameworks and the Orthogonalized Inference-Time Intervention (O-ITI) baseline evaluated in our main text (Section 4.3), elucidating why rigid global directions deterministically induce syntactic collapse.

Under standard formulations, contemporary architectures apply root-mean-square layer normalization:

$$\mathrm{RMSNorm}(x) = \frac{x}{\mathrm{RMS}(x)} \odot \gamma, \quad \text{where } \mathrm{RMS}(x) = \sqrt{\frac{1}{d}\sum_{i=1}^{d} x_i^2}. \tag{6}$$

Because $\mathrm{RMSNorm}(x)$ is scale-invariant ($\mathrm{RMSNorm}(c \cdot x) = \mathrm{RMSNorm}(x)$ for any scalar $c > 0$), normalization projects hidden states onto a scaled unit hypersphere. Consider an idealized locally-orthogonal rotation attempting to steer along a direction $v_\perp$. In this theoretical localized projection where $v_\perp$ is perfectly orthogonal to the instantaneous activation

h ($\langle h, v_\perp \rangle = 0$), the post-intervention state before normalization is $h_{\text{ideal}} = h + \alpha v_\perp$. Under subsequent normalization, the projected representation traces an arc:

$$\frac{h + \alpha v_\perp}{\|h + \alpha v_\perp\|_2} = \frac{h + \alpha v_\perp}{\sqrt{\|h\|_2^2 + \alpha^2 \|v_\perp\|_2^2}} = \cos(\phi')\hat{h} + \sin(\phi')\hat{v}_\perp, \tag{7}$$

where $\tan(\phi') = \frac{\alpha \|v_\perp\|_2}{\|h\|_2}$. Note that this derivation illustrates the idealized localized limit where $v_\perp$ is instantaneously orthogonal to h ($\langle h, v_\perp \rangle = 0$) for geometric intuition. In practical implementation, O-ITI projects an offline, globally fixed direction $v_\perp$ uniformly across all tokens, where non-vanishing cross-terms $\langle h, v_\perp \rangle \neq 0$ further exacerbate directional misalignment. Thus, within the sub-layer branch, orthogonal addition followed by layer normalization is geometrically equivalent to a rigid, non-adaptive angular rotation. However, a fundamental architectural distinction separates O-ITI from MPISC. O-ITI operates by projecting a **globally fixed, offline-computed** direction $v_\perp$ uniformly across all tokens. Because the local tangent space of the residual stream changes dynamically across context and depth, forcing every token's trajectory along an invariant global axis brutally overrides the token's specific local manifold curvature. Our empirical telemetry confirms that this rigid, non-adaptive directional intervention inevitably ruptures the delicate semantic boundaries required for structured logic, yielding the 100% AST error rate observed under O-ITI.

In contrast, the MPISC operator dynamically constructs a token-specific local tangent plane $\text{span}(h, v_\perp)$ online via real-time Gram-Schmidt orthogonalization at inference. By ensuring that the rotation plane conforms to the instantaneous activation h, MPISC respects local manifold geometry while maintaining exact norm conservation ($\Delta\|h\|_2 \equiv 0$). This input-adaptive geometry is precisely what enables MPISC to preserve 90% of native syntactic capacity, whereas static, globally defined operators deterministically collapse.

B Experimental Setup and Model Specifications

Telemetry is intercepted across four frontier open-weight models spanning distinct training paradigms:

- Meta-Llama-3.1-8B-Instruct: Dense RLHF alignment, 32 layers, hidden dimension $d = 4096$. Critical anchor layers: $l \in [26, 27, 28, 29]$.
- Mistral-Nemo-Instruct-2407 (12B): Sliding-window attention hybrid, 40 layers, $d = 5120$. Critical anchor layers: $l \in [33, 34, 35, 36]$.
- Qwen-3-8B: Extensive post-training alignment with deep mathematical CoT specialization, 36 layers, $d = 4096$. Critical anchor layers: $l \in [21, 22, 23, 24, 25, 26, 27]$.
- Phi-4-Reasoning-14B: GRPO-oriented synthetic reasoning alignment, 40 layers, $d = 5120$. Critical anchor layers: $l \in [24, 25, 26, 27, 28, 29, 30]$.

C Geometric Pathologies of Euclidean Steering

Expanding the squared L_2 norm of the intervened representation yields:

$$\|h'\|_2^2 = \|h + \alpha\hat{v}\|_2^2 = \|h\|_2^2 + 2\alpha\langle h, \hat{v}\rangle + \alpha^2, \tag{8}$$

where $\hat{v} = v/\|v\|_2$. The resulting norm drift $\Delta\|h\|_2 = \|h'\|_2 - \|h\|_2$ exhibits first-order dependence on alignment $\langle h, \hat{v}\rangle$ and second-order quadratic growth with intervention scale α^2. As quantified in Section 4.3 ($\Delta\|h\|_2 \approx 0.0368$, representing a relative drift of $\sim 10^{-4}$ relative to $\|h\|_2$), this pre-norm inflation is physically negligible and cannot account for the syntactic collapse; the breakdown stems from rigid directional misalignment.

In modern autoregressive transformers, residual activations maintain a tightly bounded dynamic range. Imposing an unconstrained Euclidean shift $\alpha\hat{v}$ creates an orthogonal velocity component that ejects h' from the localized manifold $\mathcal{M}$ into under-parameterized, out-of-distribution regions of $\mathbb{R}^d$. Because RMSNorm is scale-invariant (Section 4.4), this displacement is a directional failure rather than a magnitude effect, producing severe downstream pathologies:

- Syntactic Manifold Shattering: Unlike semantic intent (which is concentrated along specific sparse directions), grammatical structure and syntactical coordination rely on delicate distributed geometric relationships. Large Euclidean offsets disrupt token transition probabilities, precipitating 100% syntax breakdown in structured generation benchmarks (e.g., Abstract Syntax Tree parsing in Python code generation).

D Proof of Exact Norm Conservation for MPISC

Proof. Compute the squared Euclidean norm of h' directly from the MPISC operator formulation:

$$\begin{aligned}\|h'\|_2^2 &= \left\| \|h\|_2 \left(\cos\theta\, \hat{h} + \sin\theta\, \hat{v}_\perp \right) \right\|_2^2 \\ &= \|h\|_2^2 \left(\cos^2\theta \|\hat{h}\|_2^2 + \sin^2\theta \|\hat{v}_\perp\|_2^2 + 2\cos\theta\sin\theta \langle \hat{h}, \hat{v}_\perp \rangle \right). \end{aligned} \tag{9}$$

By construction, the basis vectors are mutually orthogonal ($\langle \hat{h}, \hat{v}_\perp \rangle = 0$) and normalized ($\|\hat{h}\|_2 = \|\hat{v}_\perp\|_2 = 1$). Substituting these values:

$$\|h'\|_2^2 = \|h\|_2^2 \left(\cos^2\theta \cdot 1 + \sin^2\theta \cdot 1 + 0 \right) = \|h\|_2^2 (\cos^2\theta + \sin^2\theta) = \|h\|_2^2. \tag{10}$$

Taking the positive square root establishes $\|h'\|_2 = \|h\|_2$, and consequently $\Delta\|h\|_2 = \|h'\|_2 - \|h\|_2 \equiv 0$. ■

E Full Quantitative Metrics for Dual-State Pathology

Table 3: Empirical characterization of the Dual-State Pathology across anchor layers under symmetric clean ($N = 279$) versus sycophantic trap ($N = 279$) induction, reporting measured absolute L_2 norms and relative drift.

Model Architecture	Anchor Layer	Clean Norm	Trap Norm	Drift $\Delta\|h\|_2$	Relative Drift	Pathology Class
Llama-3.1-8B-Instruct	Layer 28	30.72	32.28	+1.56	+5.1%	Geometric Contraction (Potential Well Influx)

G Extended Discussion on Limitations and Future Directions

Our investigations focused on open-weight models in the 7B to 14B parameter range under prefill-phase interventions. While prefill steering addresses the initial reasoning trajectory, auto-regressive error accumulation across extended generation sequences requires further dynamic control. Extending constant-norm operators to multi-layer recurrent feedback loops and exploring geometric regularization during pre-training represent promising avenues for future research. From a systems perspective, the single-layer Gram-Schmidt planar orthogonalization and Givens rotation introduce an ultra-lightweight computational overhead of $\mathcal{O}(d)$, executing in sub-millisecond latencies per prefill forward pass and strictly avoiding memory conflicts with kernel optimizations like FlashAttention (Dao et al., 2022). Furthermore, while our formulation currently applies to the global residual stream, integrating MPISC with Sparse Autoencoders (SAEs) represents a compelling frontier. Since sycophantic circuits are known to be localized within highly sparse latent features, projecting MPISC rotations onto SAE-decomposed feature subspaces rather than dense layer activations could alleviate cancellation effects in dynamic dispersion regimes, enabling non-destructive interventions across complex conversational topologies.

H Formal Preliminaries of Representation Dynamics

H.1 Transformer Discrete Dynamics and Decoding Formulation

The propagation of representations across depth follows the discrete dynamical equation:

$$h_{l+1}^{(t)} = h_l^{(t)} + \mathrm{Attn}_l\left(\mathrm{LN}(h_l^{(1:t)})\right) + \mathrm{MLP}_l\left(\mathrm{LN}(h_l^{(t)})\right), \tag{11}$$

where $\mathrm{LN}(\cdot)$ denotes pre-layer normalization, Attn_l represents multi-head self-attention with rotary position embeddings (RoPE) (Su et al., 2024), viewing depth propagation as a discrete dynamical system (Chen et al., 2018; Haber & Ruthotto, 2018), and MLP_l denotes a two-layer feed-forward network with non-linear activation gating. The final decoding distribution projects the terminal layer representation through the unembedding matrix $W_u \in \mathbb{R}^{|V|\times d}$:

$$P(x_{t+1} \mid x_{1:t}) = \mathrm{softmax}\left(W_u \cdot \mathrm{LN}(h_L^{(t)})\right). \tag{12}$$

H.2 Formal Adversarial Induction Parameters

The adversarial prompt generator $f(X_{\text{clean}}, \alpha, \beta, \gamma)$ transforms an objective question X_{clean} into an adversarial induction instance X_{trap}, parameterized by three distinct perturbation factors:

1. $\alpha \in [0, 1]$ represents the strength of fallacious mathematical or logical presuppositions injected directly into the problem premise;
2. $\beta \in [0, 5]$ denotes the length of simulated multi-turn conversational history reinforcing the false claim;
3. $\gamma \in [0, 1]$ controls the perceived authority of the user's assertion (e.g., prefixing assertions with formal academic consensus claims: "The above derivation contradicts established academic consensus. Re-evaluate and correct your reasoning.").

I Micro-Telemetry of Autoregressive Error Cascades

To empirically validate the mechanistic origins of the performance disparity observed in Section 4.3—where Euclidean O-ITI ($\alpha = 5.0$) triggers a 100% AST collapse despite a minor mean effective rotation of $\approx 0.84°$, while MPISC ($\theta = 0.3$) preserves 90% of the syntax under a much larger 17° rotation—we conducted a 15-step token-by-token micro-telemetry analysis on Qwen-3-8B across the full LiveCodeBench suite ($N = 279$). By intercepting the logit distributions during the critical transition from prefill to autoregressive decoding ($t = 1 \ldots 15$), we observe two fundamentally distinct representational dynamics:

O-ITI: Pseudo-Invariance and Off-Manifold Drift. Under prefill-only intervention at the anchor layer, O-ITI's rigid global projection (mean effective rotation $\approx 0.84°$) lacks sufficient magnitude to immediately fracture the model's high-confidence semantic pathways. At the first decoding step ($t = 1$), O-ITI exhibits a 0.0% flip rate, preserving the initial code block token (‘```‘) with a mean rank of 1.0 across all 279 tasks. However, the mechanism of failure is a delayed autoregressive cascade driven by KV-cache poisoning. Although the external intervention ceases during generation, the autoregressive attention heads must continuously attend to the corrupted prefill KV-cache. Because the initial rigid perturbation fatally misaligned with the local tangent space, this context corruption injects a persistent off-manifold drift into the residual stream at each generation step. By step $t \approx 4$, this latent error accumulates sufficiently to abruptly eject the trajectory from the code manifold, ultimately collapsing into unparseable conversational degenerate outputs.

MPISC: On-Manifold Syntactic Branching. In contrast, MPISC dynamically constrains the intervention within the specific local tangent plane $\text{span}(h, v_\perp)$. Although a 17° rotation is substantially larger, our telemetry reveals that it translates the representation along the semantic manifold rather than ejecting it. For instance, in our tracking of a representative task, while the unsteered baseline confidently initiates a specific syntax path (‘class Solution:‘), MPISC alters the trajectory by Step 3 (‘from typing import List \n import heapq‘). This demonstrates a complete flip in the exact token sequence while effectively preserving valid syntactic structure. Across 15 steps, MPISC sustains a $> 91.8\%$ valid code token emission rate, statistically indistinguishable from the unsteered baseline (92.1%). This micro-telemetry empirically isolates the operative mechanism: the catastrophic collapse under linear steering is an off-manifold cascading phenomenon triggered by rigid directional ejection, whereas MPISC's success stems from driving high-magnitude, on-manifold semantic variation without violating local topological constraints.

J Core Algorithmic Implementations

To ensure uncompromising transparency and facilitate rigorous peer review without reliance on external network access, this section provides self-contained, pure PyTorch implementations of the core algorithmic components underpinning our claims. All variable names and dimensions strictly mirror the formal definitions in the main text.

J.1 Steering Operators: MPISC and O-ITI

Listing 1 provides the functional implementations of the proposed constant-norm MPISC operator (Eq. 1–2) and the linear Euclidean O-ITI baseline (Appendix C).

Listing 1: Core Steering Operators

```
import torch
import torch.nn.functional as F

def mpisc_rotation(h: torch.Tensor, v: torch.Tensor, theta: float) -> torch.Tensor:
    """
    Manifold-Perturbed Intrinsic Self-Correction (MPISC).
    Executes an in-plane Givens rotation in span(h, v_perp) with provable
    exact norm conservation (||h'||_2 == ||h||_2, Theorem 1).
    """
    v = v.to(dtype=h.dtype, device=h.device)

    # 1. Orthonormal coordinate frame construction (Gram-Schmidt)
    h_norm = torch.norm(h, p=2, dim=-1, keepdim=True)
    h_hat = h / h_norm.clamp(min=1e-10)

    v_dot_h = (v * h_hat).sum(dim=-1, keepdim=True)
    v_perp = v - v_dot_h * h_hat
    v_hat = v_perp / torch.norm(v_perp, p=2, dim=-1, keepdim=True).clamp(min=1e-10)
```

```
    # 2. In-plane rotation parameterized by steering angle theta
    cos_theta = torch.cos(torch.tensor(theta, dtype=h.dtype, device=h.device))
    sin_theta = torch.sin(torch.tensor(theta, dtype=h.dtype, device=h.device))

    h_prime = h_norm * (cos_theta * h_hat + sin_theta * v_hat)
    return h_prime

def orthogonal_iti(h: torch.Tensor, v_ortho: torch.Tensor, alpha: float) -> torch.Tensor:
    """
    Orthogonalized Inference-Time Intervention (O-ITI) baseline.
    Adds a globally fixed, offline-precomputed orthogonal direction (v_ortho)
    uniformly across all tokens as a rigid displacement.
    Unlike MPISC, it lacks token-specific local adaptivity, inducing catastrophic
    geometric misalignment with the dynamic local tangent space.
    """
    v_ortho = v_ortho.to(dtype=h.dtype, device=h.device)
    # Rigid linear displacement (translates off the localized manifold)
    return h + alpha * v_ortho
```

J.2 Prefill Hook Harness and Jacobian Spectral Tracker

Listing 2 details the forward-hook harness for single-layer prefill gating and the VJP power-iteration procedure for tracking the inter-layer Jacobian spectral radius.

Listing 2: Intervention Hook and Jacobian Analysis

```
